Employee IT Support Management

ServiceNow Administrator & Developer Portfolio Project

I built a scoped ServiceNow solution to manage employee IT support requests from submission through assignment, due-date tracking, resolution, notification and reporting.

Core skills demonstrated

Scoped application | Custom table | Service Catalog | Flow Designer | Client Script | Business Rules | Import Set | Notifications | Reports | Platform Analytics

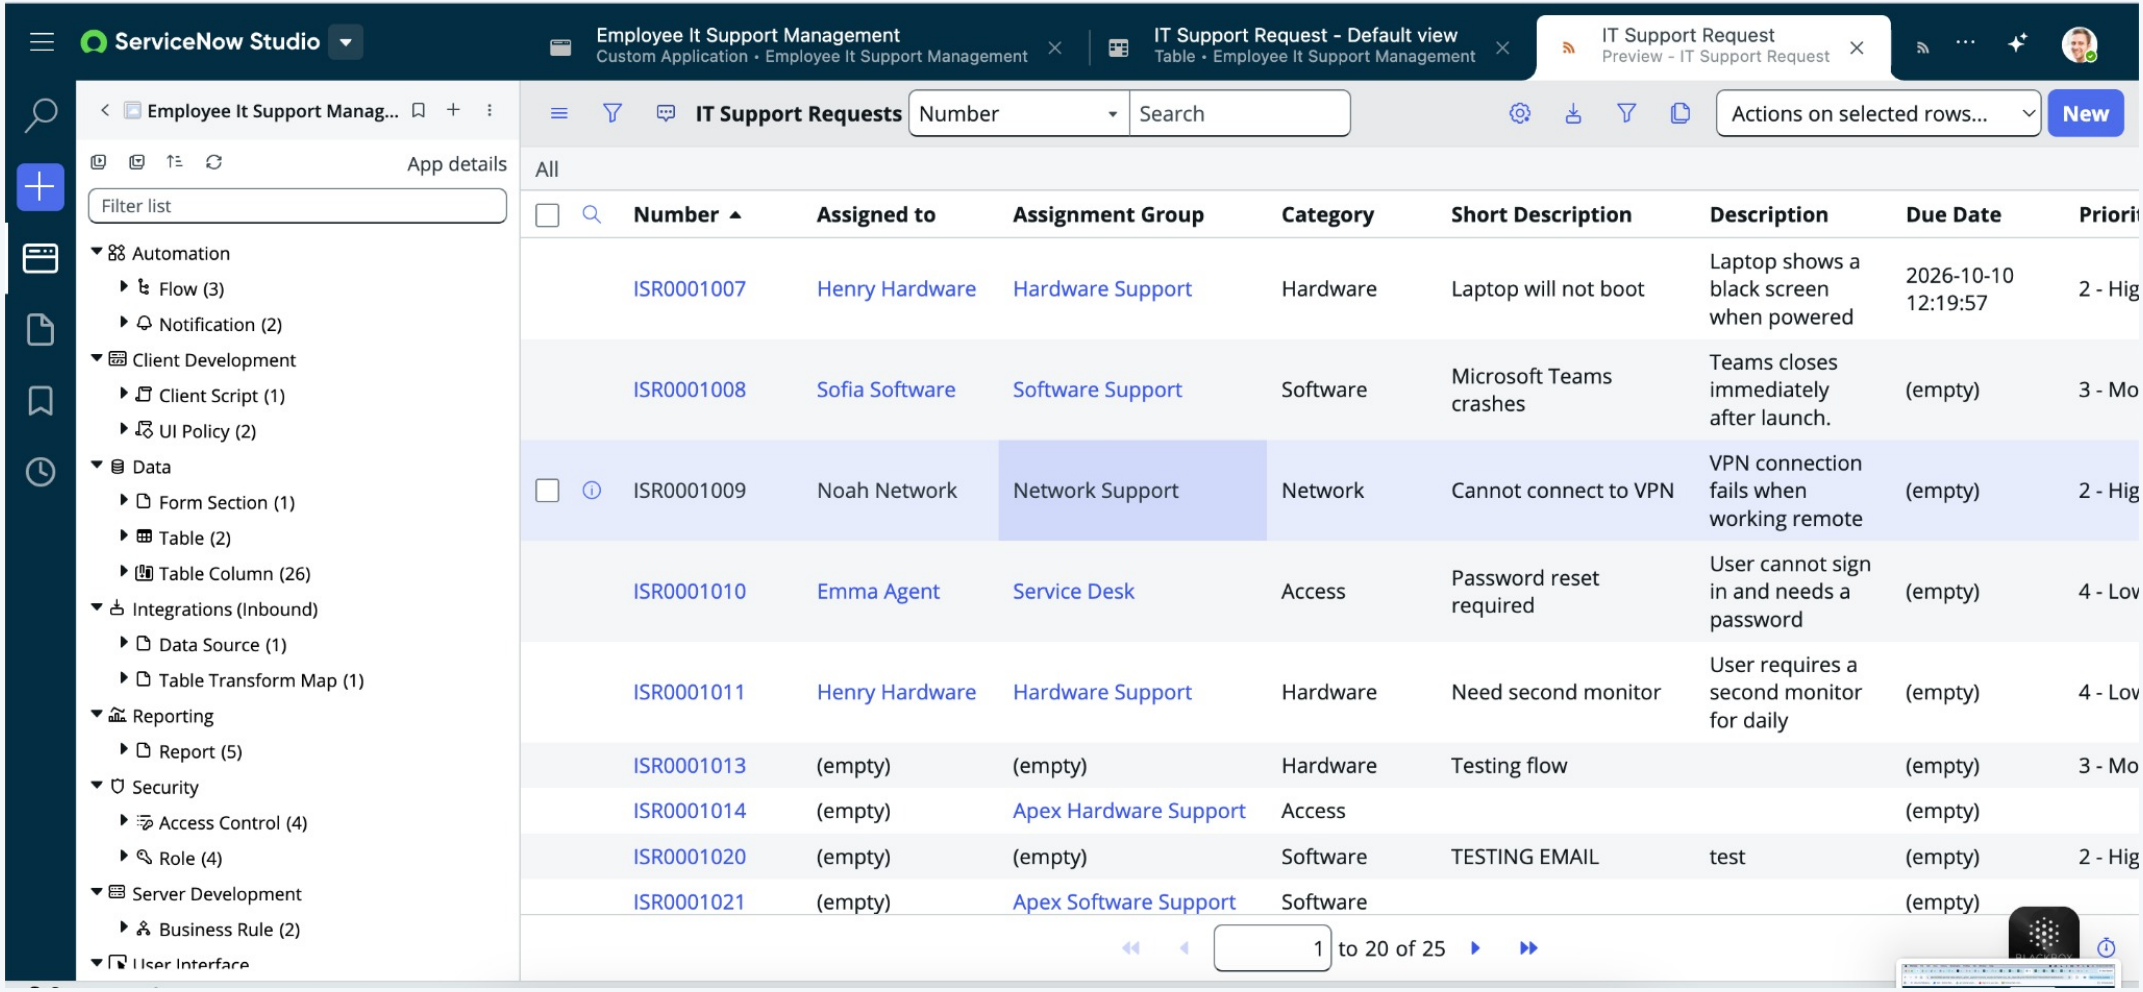

What I built

I created the Employee IT Support Management application as a complete support-request process inside ServiceNow. Employees can submit a Request IT Support catalog item, and the platform creates a custom IT Support Request record. I then automated assignment by category, calculated due dates from priority, added client-side and server-side resolution controls, created email notifications, imported sample records through an Import Set and Transform Map, and built reports and a Platform Analytics dashboard.

Process I implemented

1. Employee submits the Request IT Support catalog item.
2. Flow Designer reads the catalog variables and creates an IT Support Request.
3. Category determines the correct support group automatically.
4. Priority determines the request due date automatically.
5. Client Script and Business Rules control the resolution process.
6. Notifications, reports and dashboard provide communication and visibility.

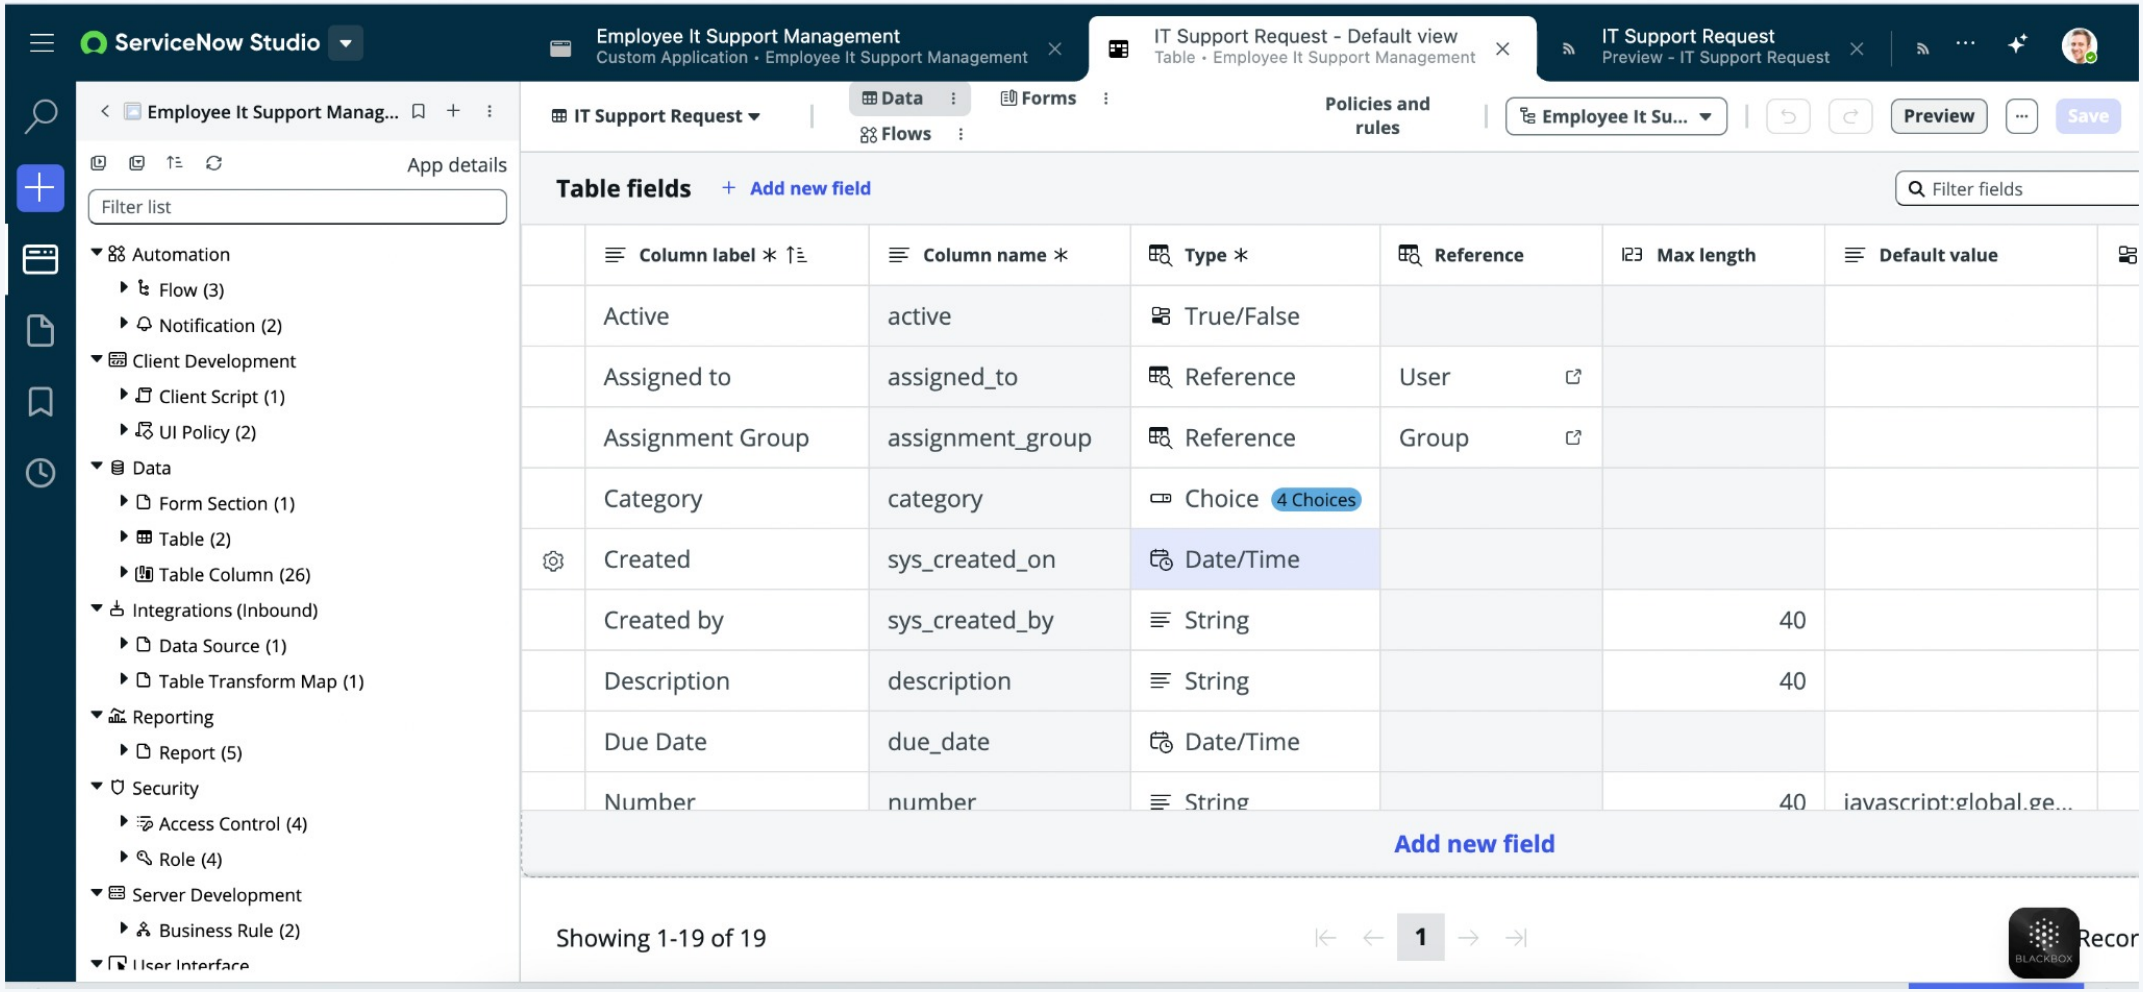

Scoped Application and Studio Structure

WHAT I DID

I built the solution inside the Employee IT Support Management application scope. In Studio I organized the custom table, flows, notifications, client script, Business Rules, reports and import components under one application. I also used sample ISR records to test assignment, priority, due-date and reporting behavior.

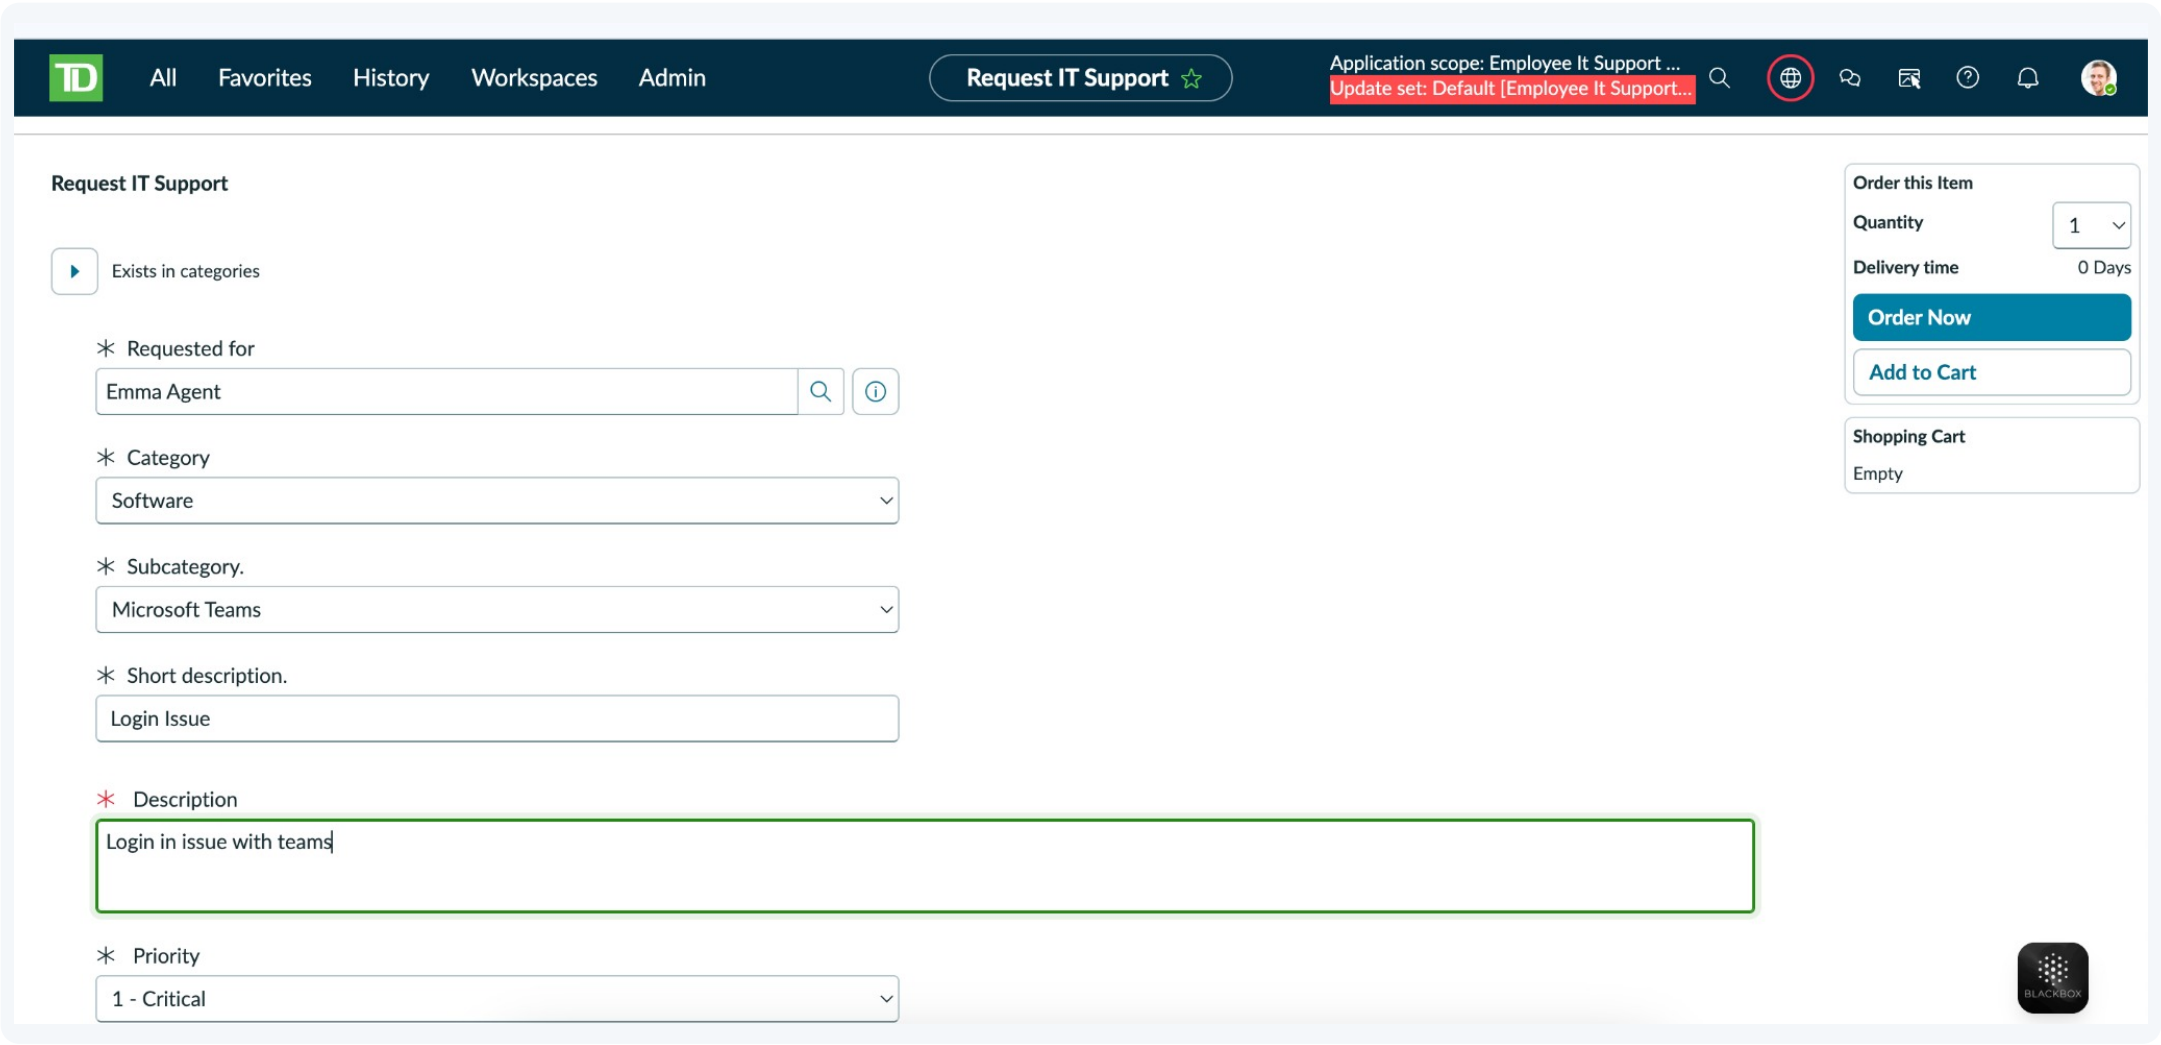

Custom IT Support Request Table

WHAT I DID

I created the IT Support Request table as the main data source for the application. I added fields for category, assignment group, assigned user, priority, state, request details, due date, resolved date, resolution notes and active status. Reference fields connect requests to ServiceNow users and groups.

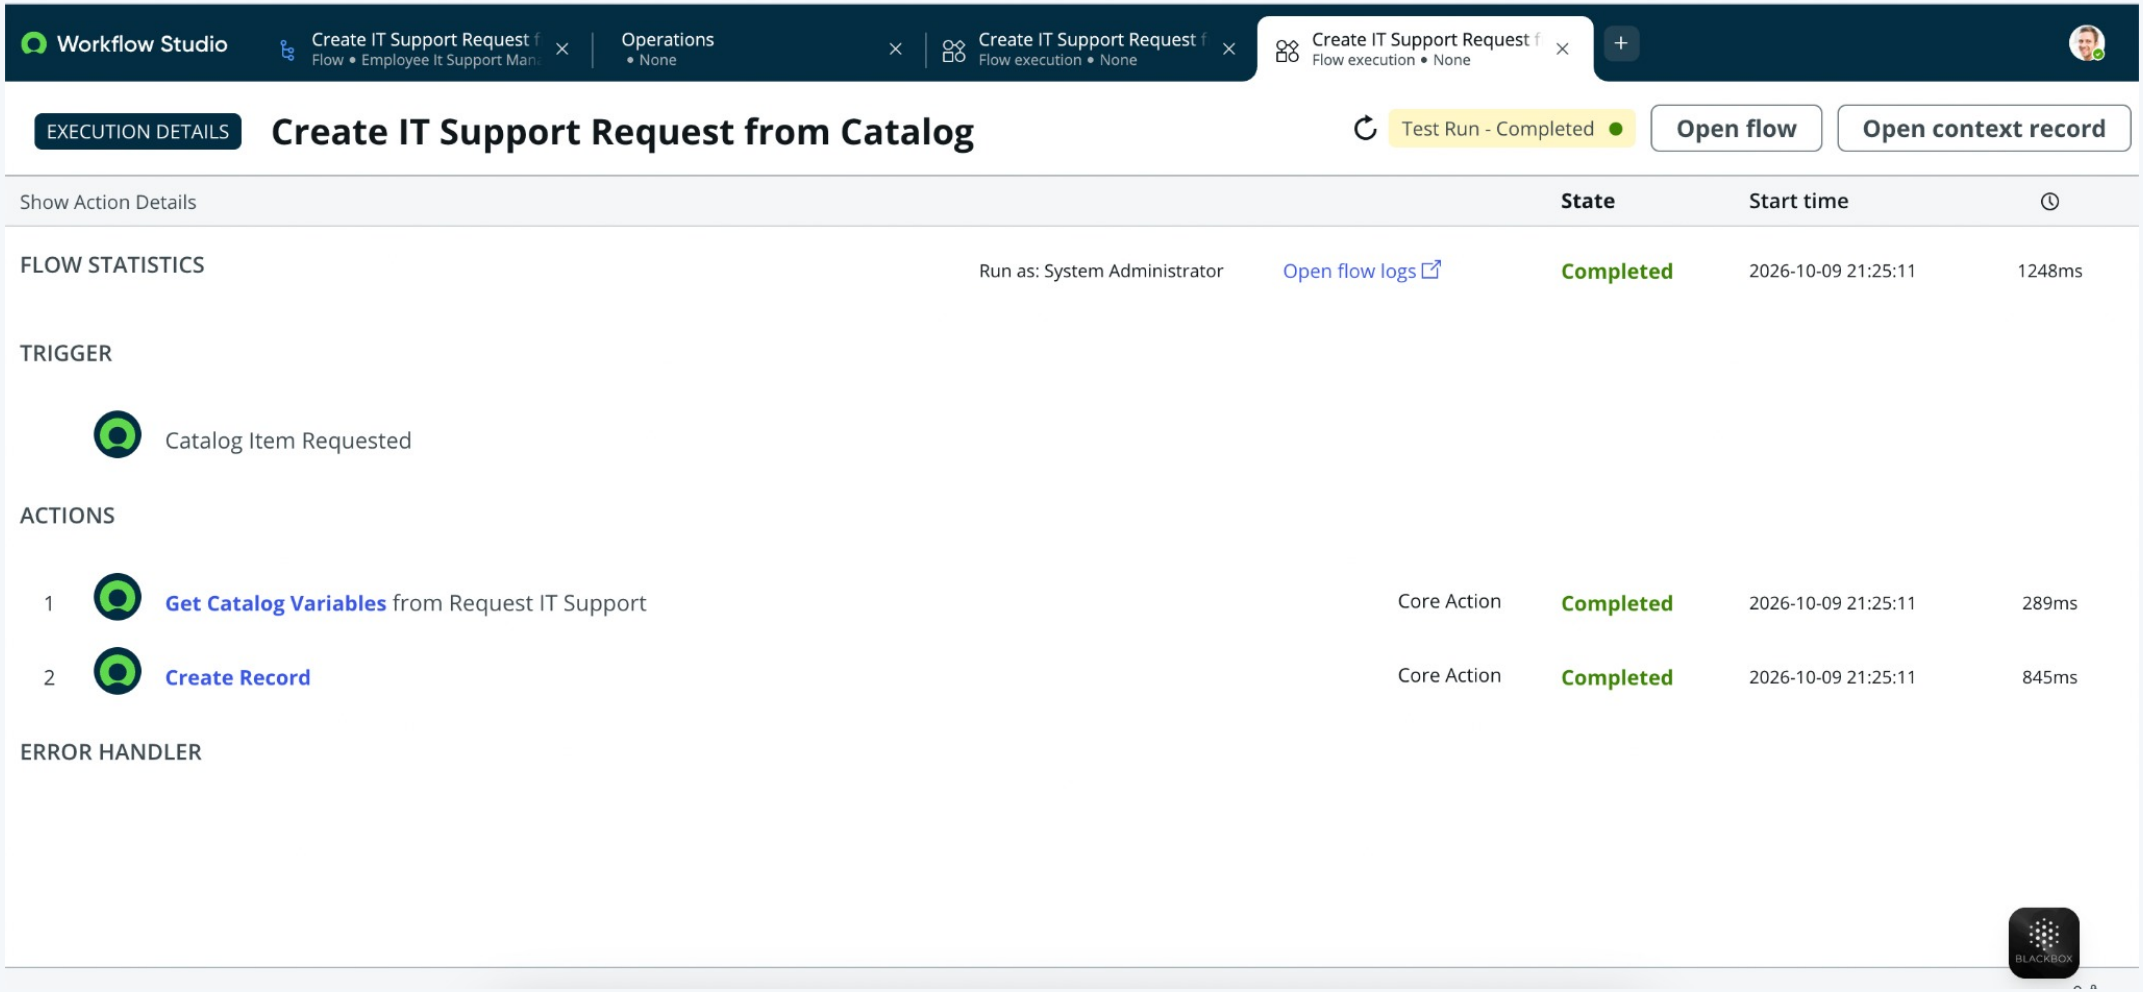

Request IT Support Catalog Item

WHAT I DID

I created a Request IT Support catalog item so employees can submit requests without working directly from the backend table. I added variables for Requested for, Category, Subcategory, Short description, Description and Priority and used those values later in Flow Designer.

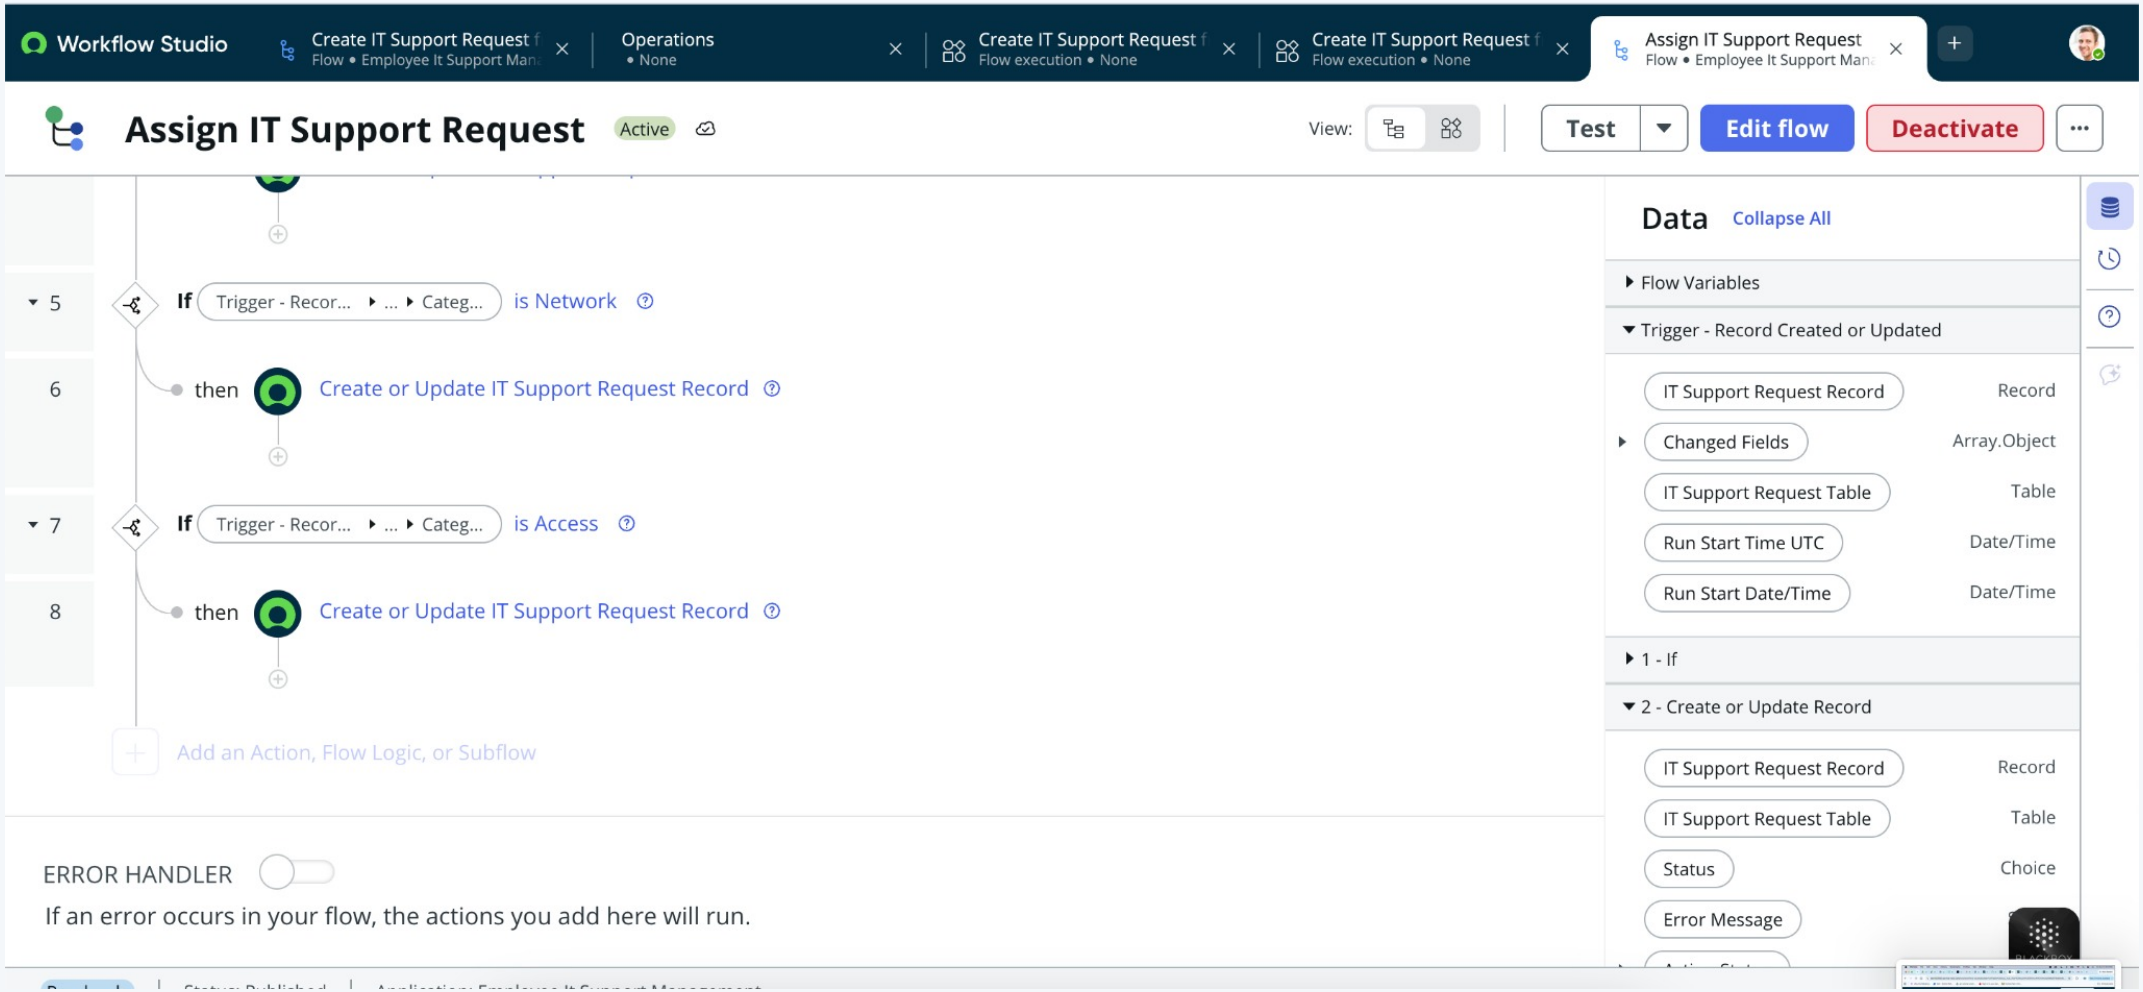

Catalog Flow Execution

WHAT I DID

I built the Create IT Support Request from Catalog flow. The Service Catalog trigger starts when the item is requested. Get Catalog Variables reads the submitted values, and Create Record creates the custom IT Support Request. I tested the flow and confirmed the trigger and both actions completed successfully.

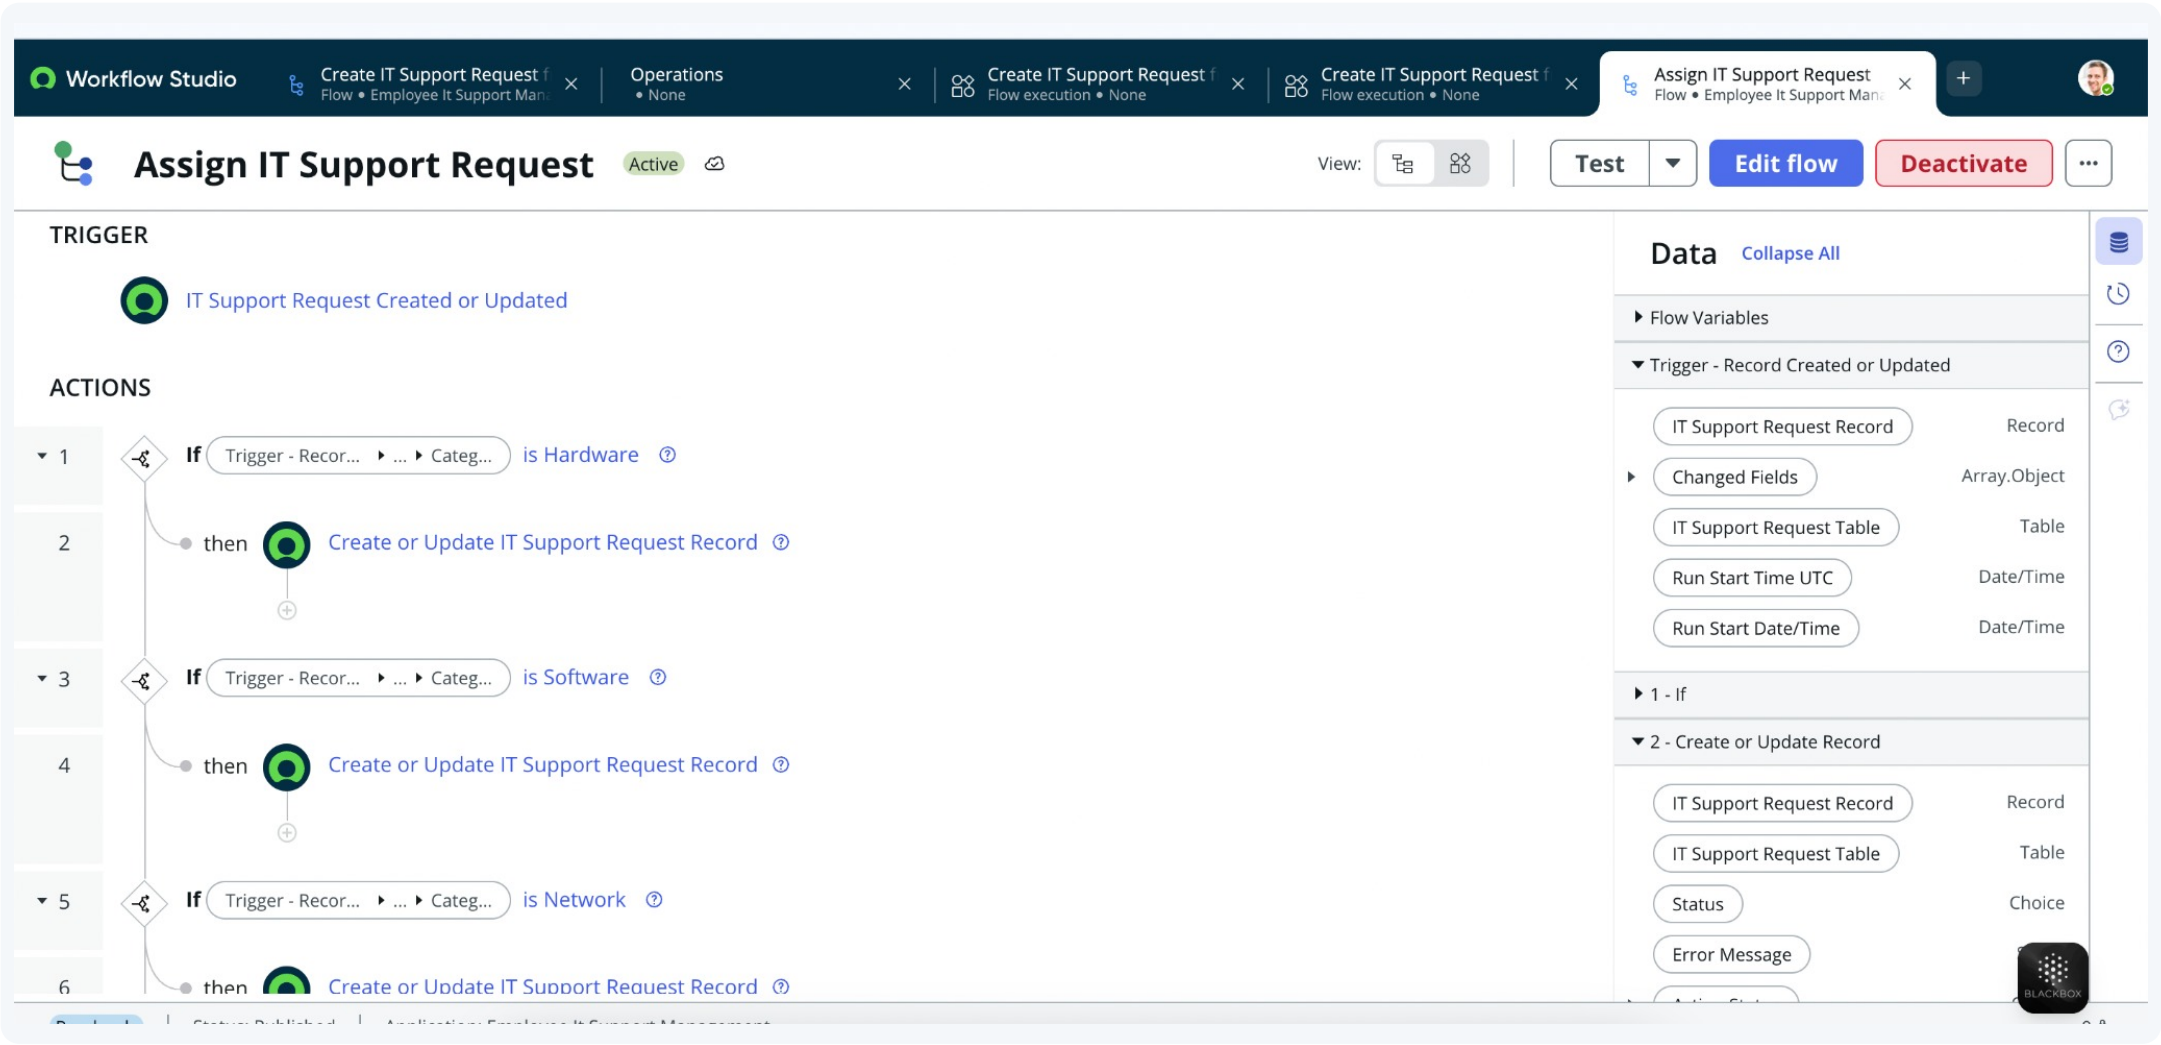

Automatic Assignment by Category - Hardware and Software

WHAT I DID

I created an Assign IT Support Request flow that checks the Category on the request. Hardware requests are routed to Hardware Support and Software requests are routed to Software Support. Each branch updates the existing request record instead of creating a second record.

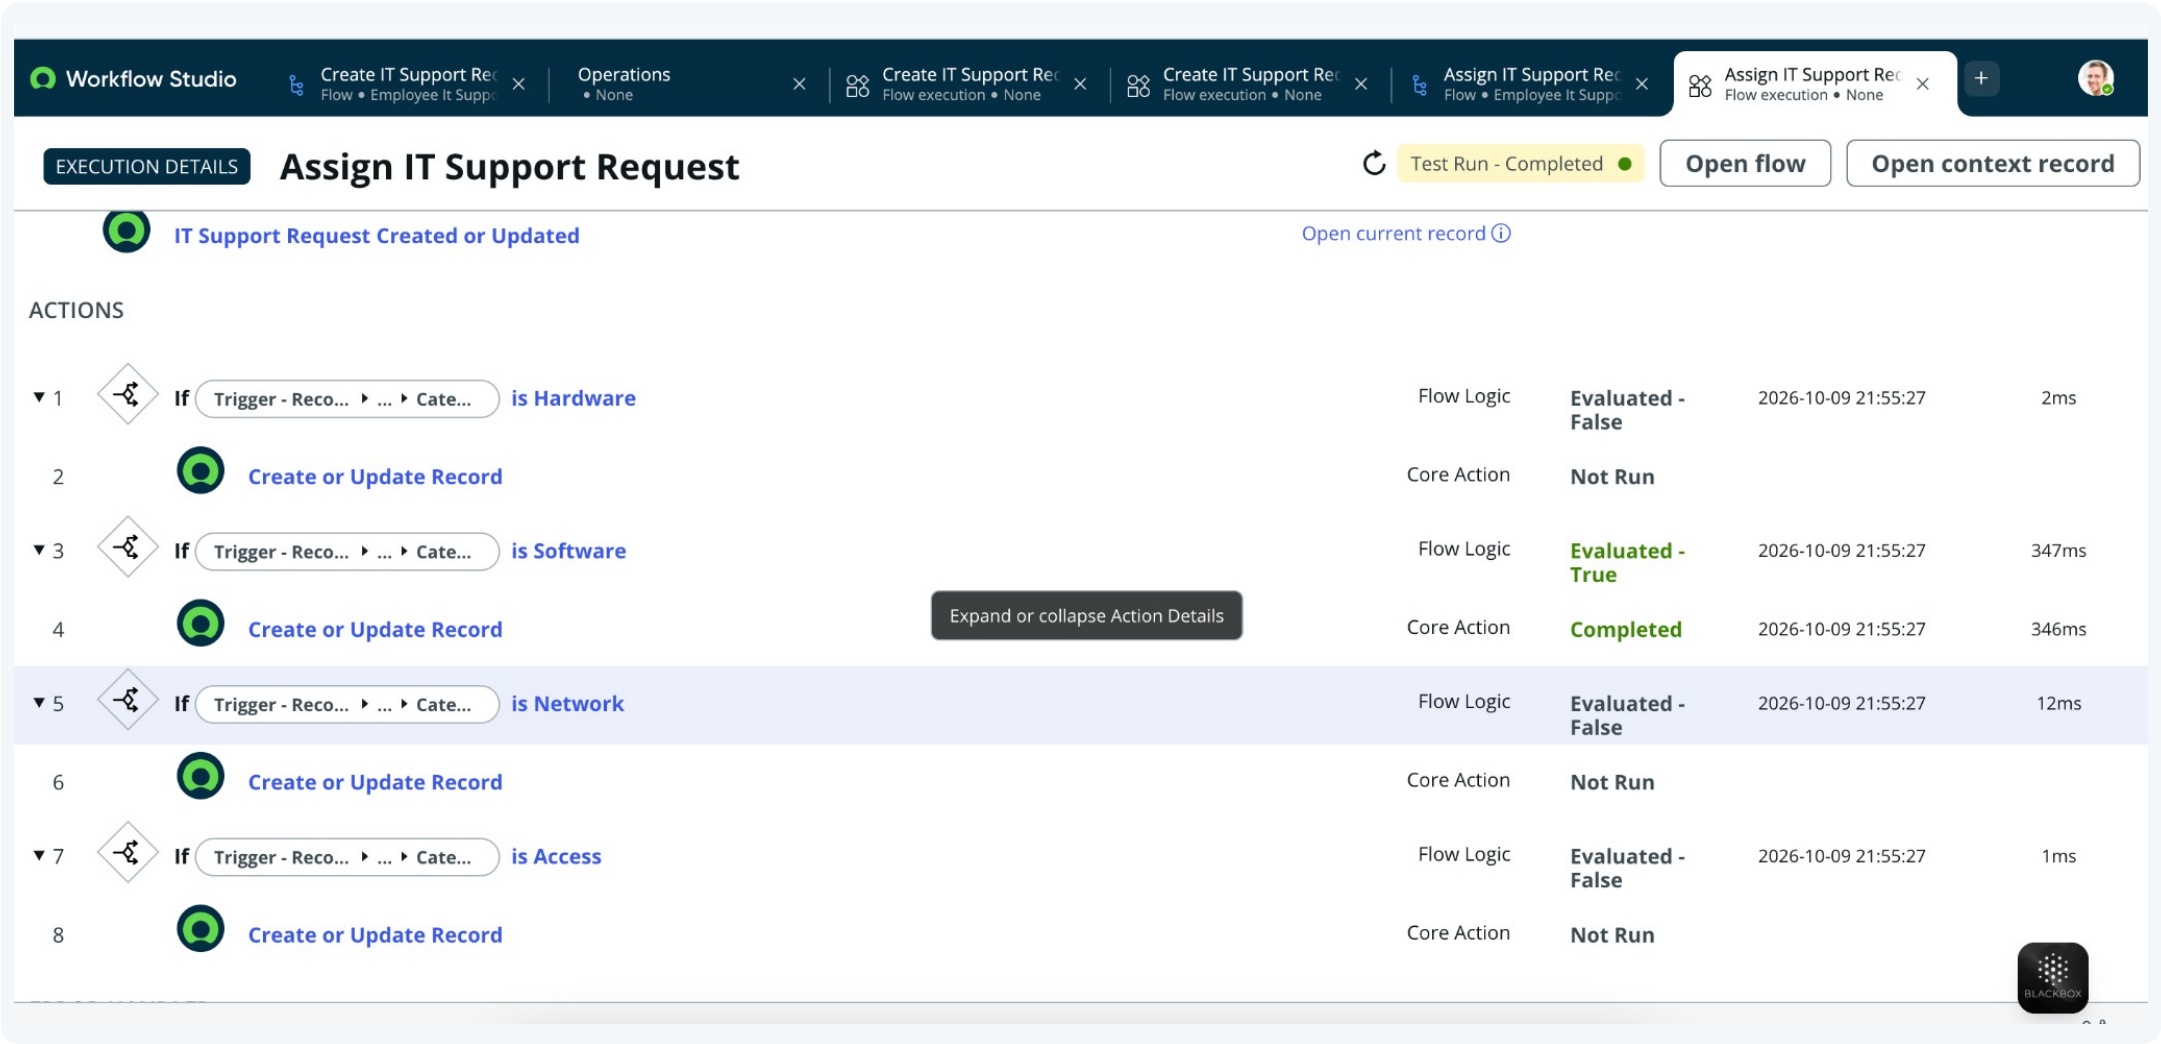

Automatic Assignment by Category - Network and Access

WHAT I DID

I continued the assignment logic for Network and Access requests. Network routes to Network Support and Access routes to Service Desk. This removes manual triage and sends the request to the correct team as soon as the category is known.

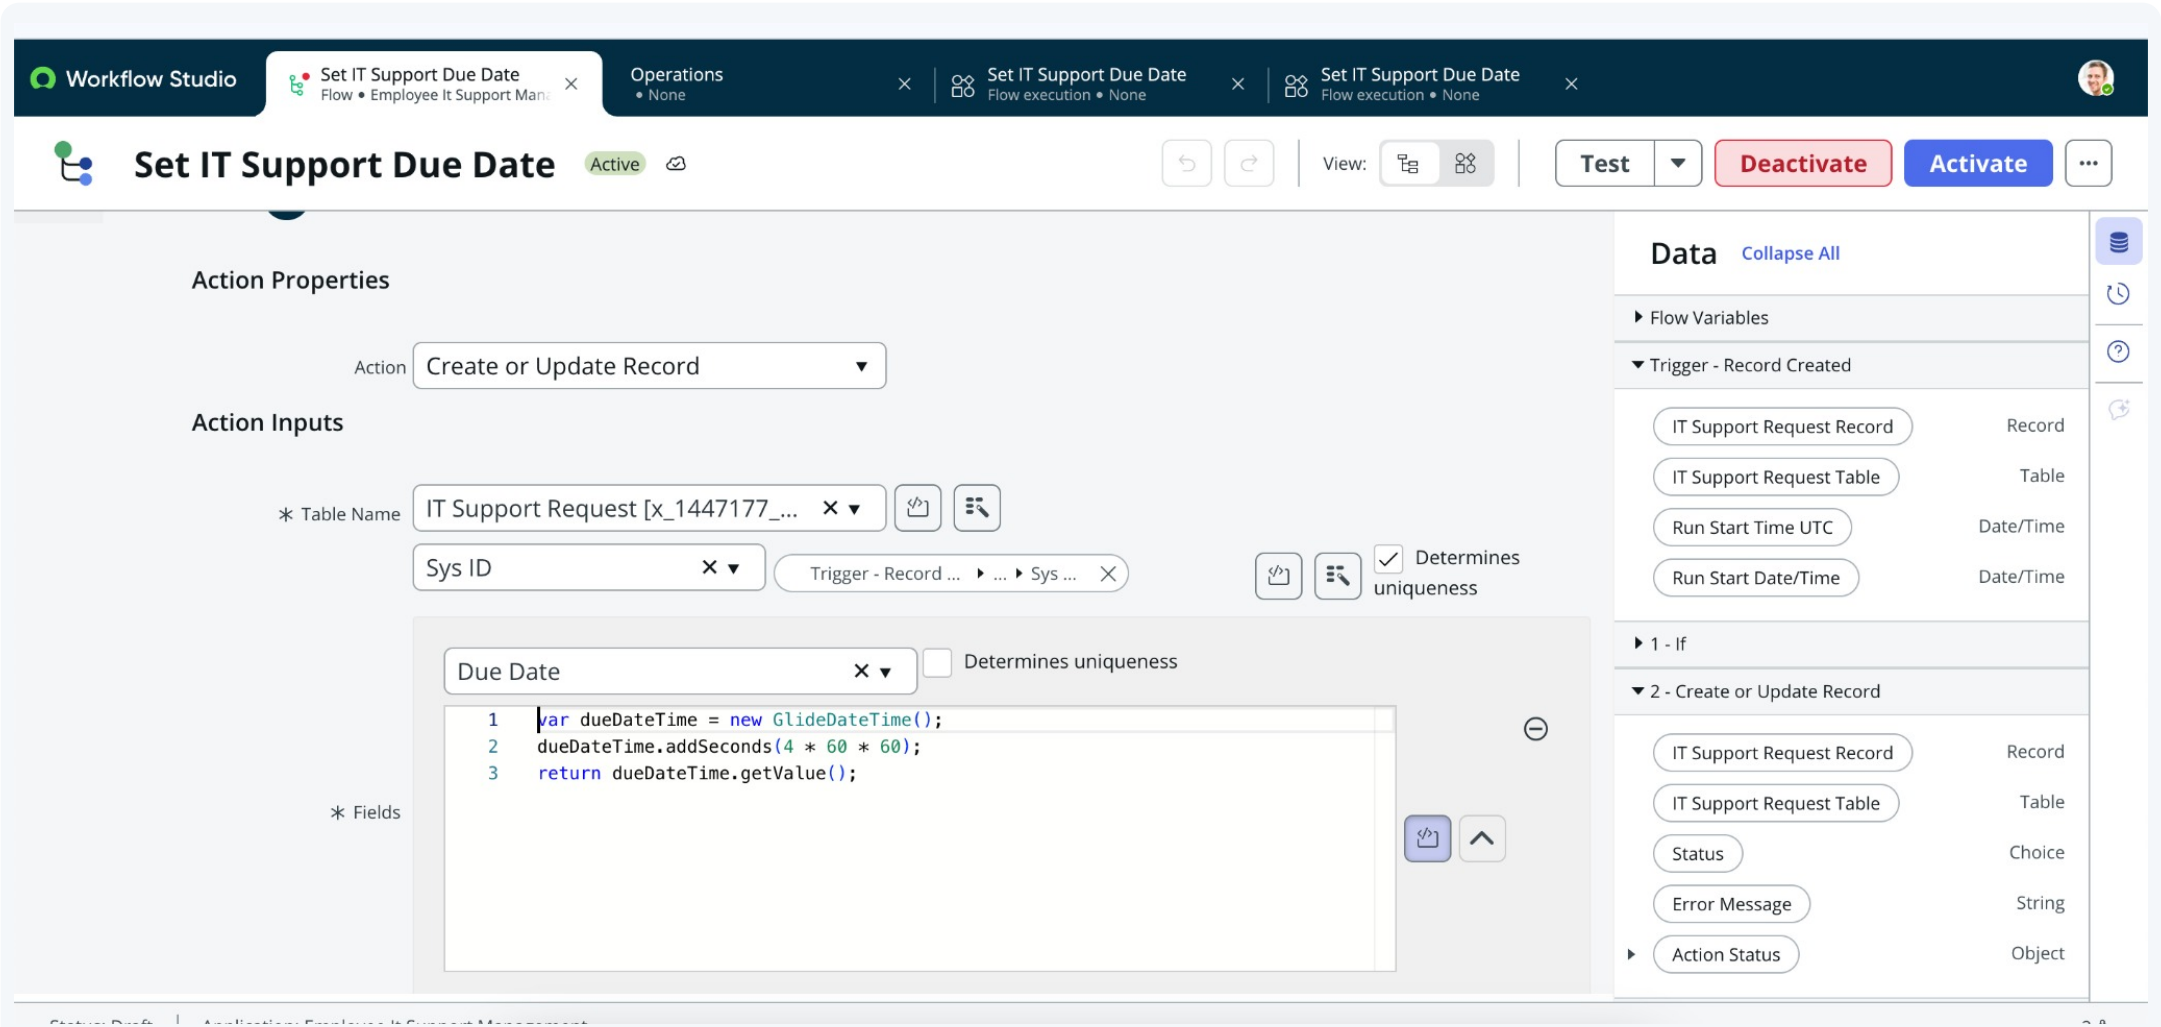

Assignment Flow Test

WHAT I DID

I tested the assignment flow with a Software request. The execution result shows the Software condition evaluated true and its update action completed, while the other category branches did not run. I used the execution details to confirm the routing logic worked correctly.

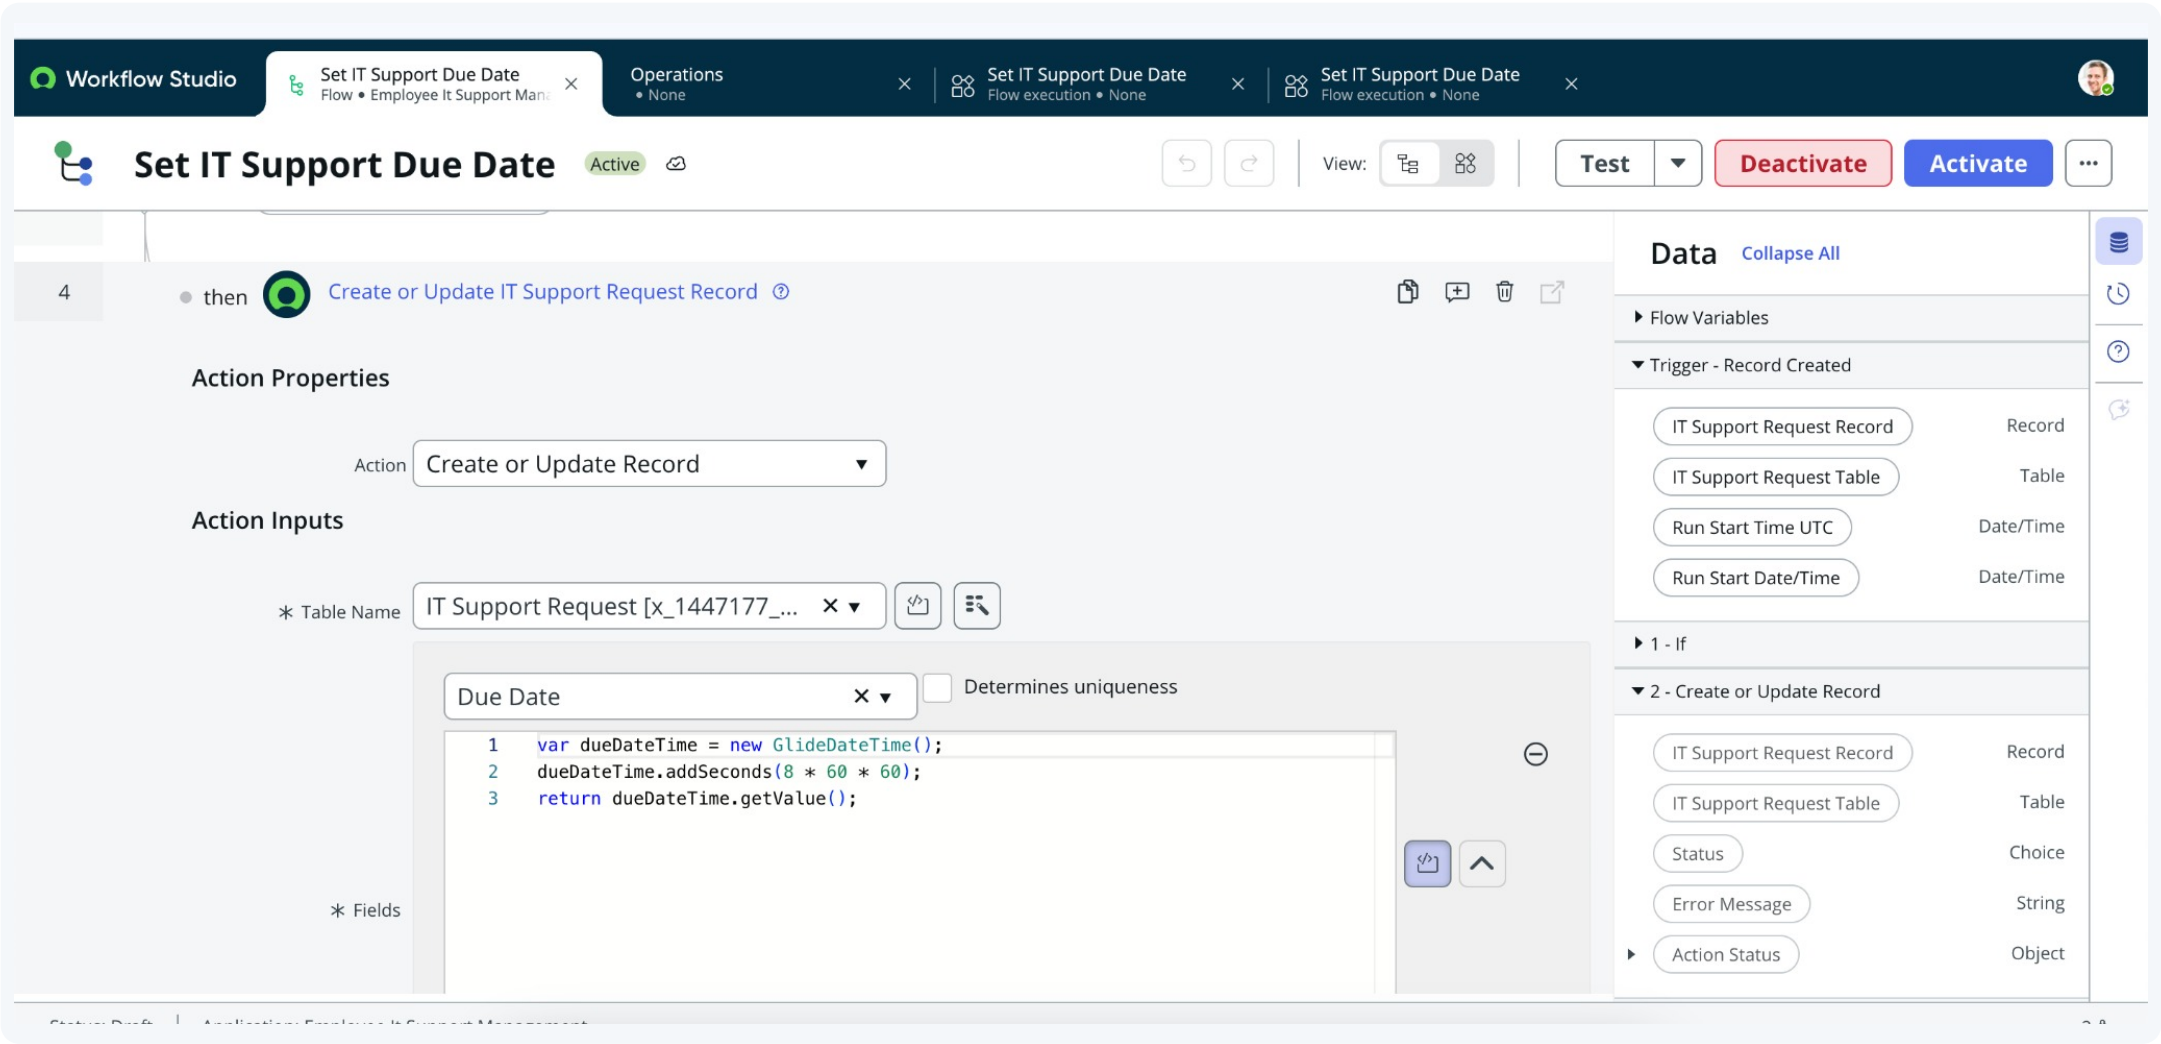

Priority 1 - Critical Due Date

WHAT I DID

For Priority 1 requests, I calculate a due date four hours from the current time. I used GlideDateTime and addSeconds() in the Flow Designer script, then updated the existing IT Support Request using its Sys ID.

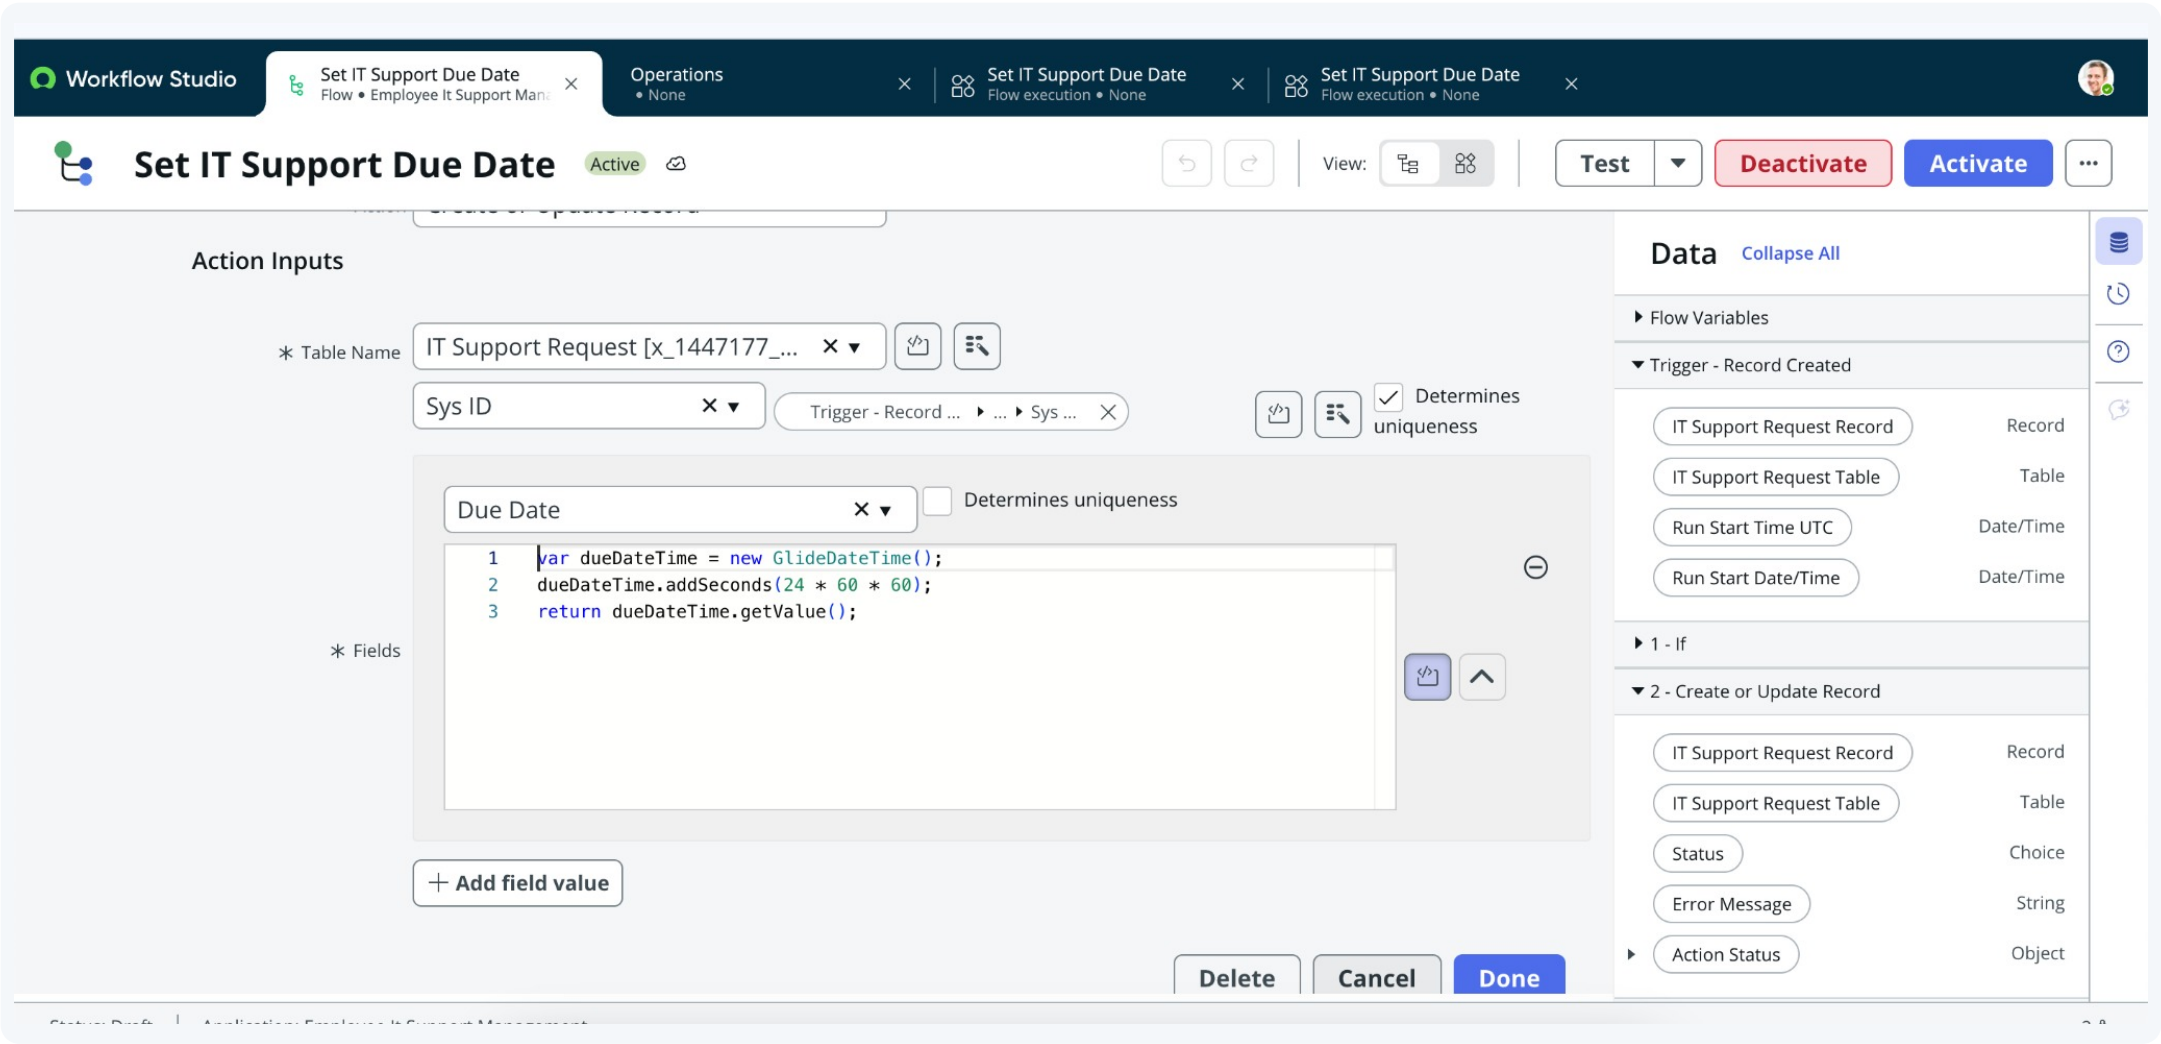

Priority 2 - High Due Date

WHAT I DID

For Priority 2 requests, I set the due date eight hours from the current time. This gives high-priority requests a shorter target while keeping the logic automatic and consistent.

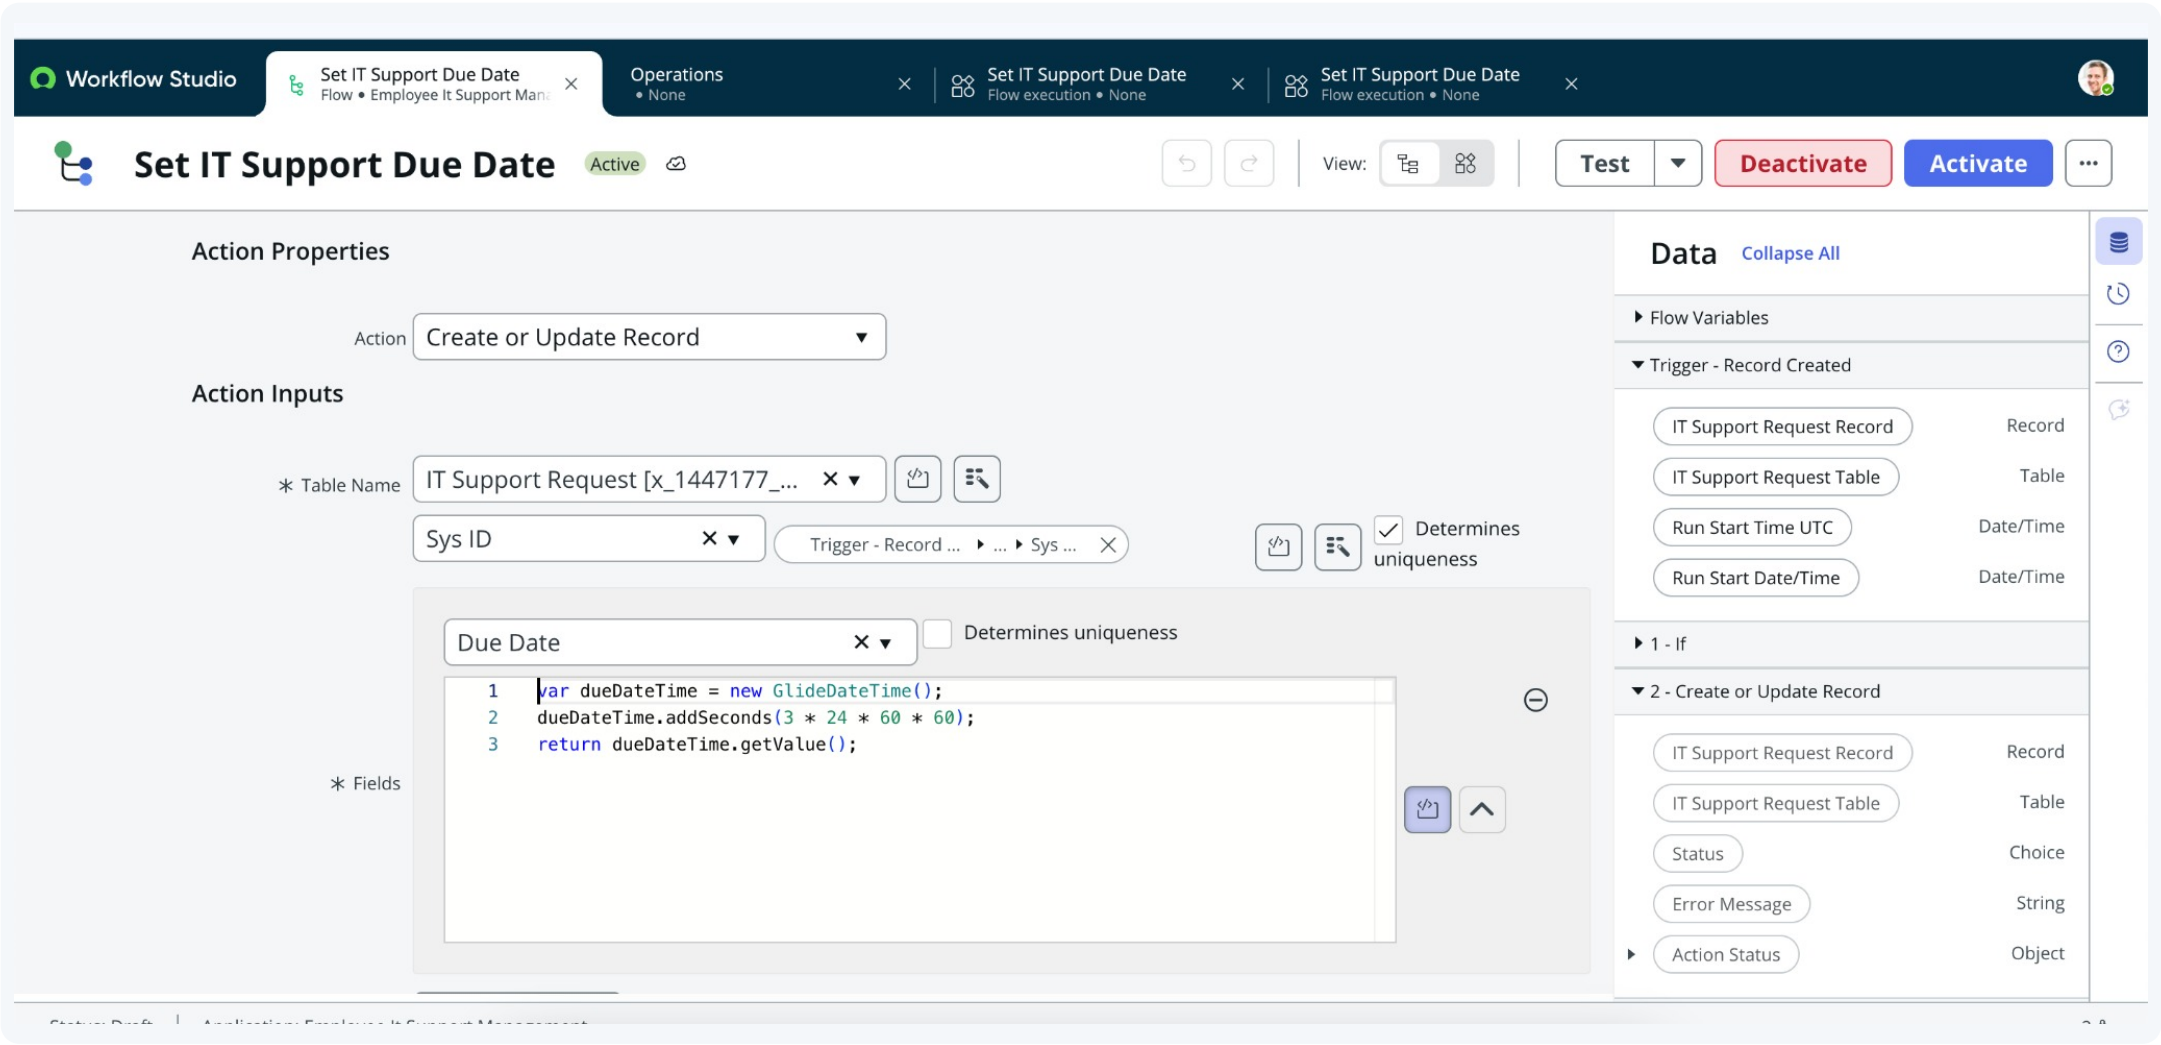

Priority 3 - Moderate Due Date

WHAT I DID

For Priority 3 requests, I set the due date twenty-four hours from the current time. The script uses GlideDateTime so the value is stored as a ServiceNow date/time value.

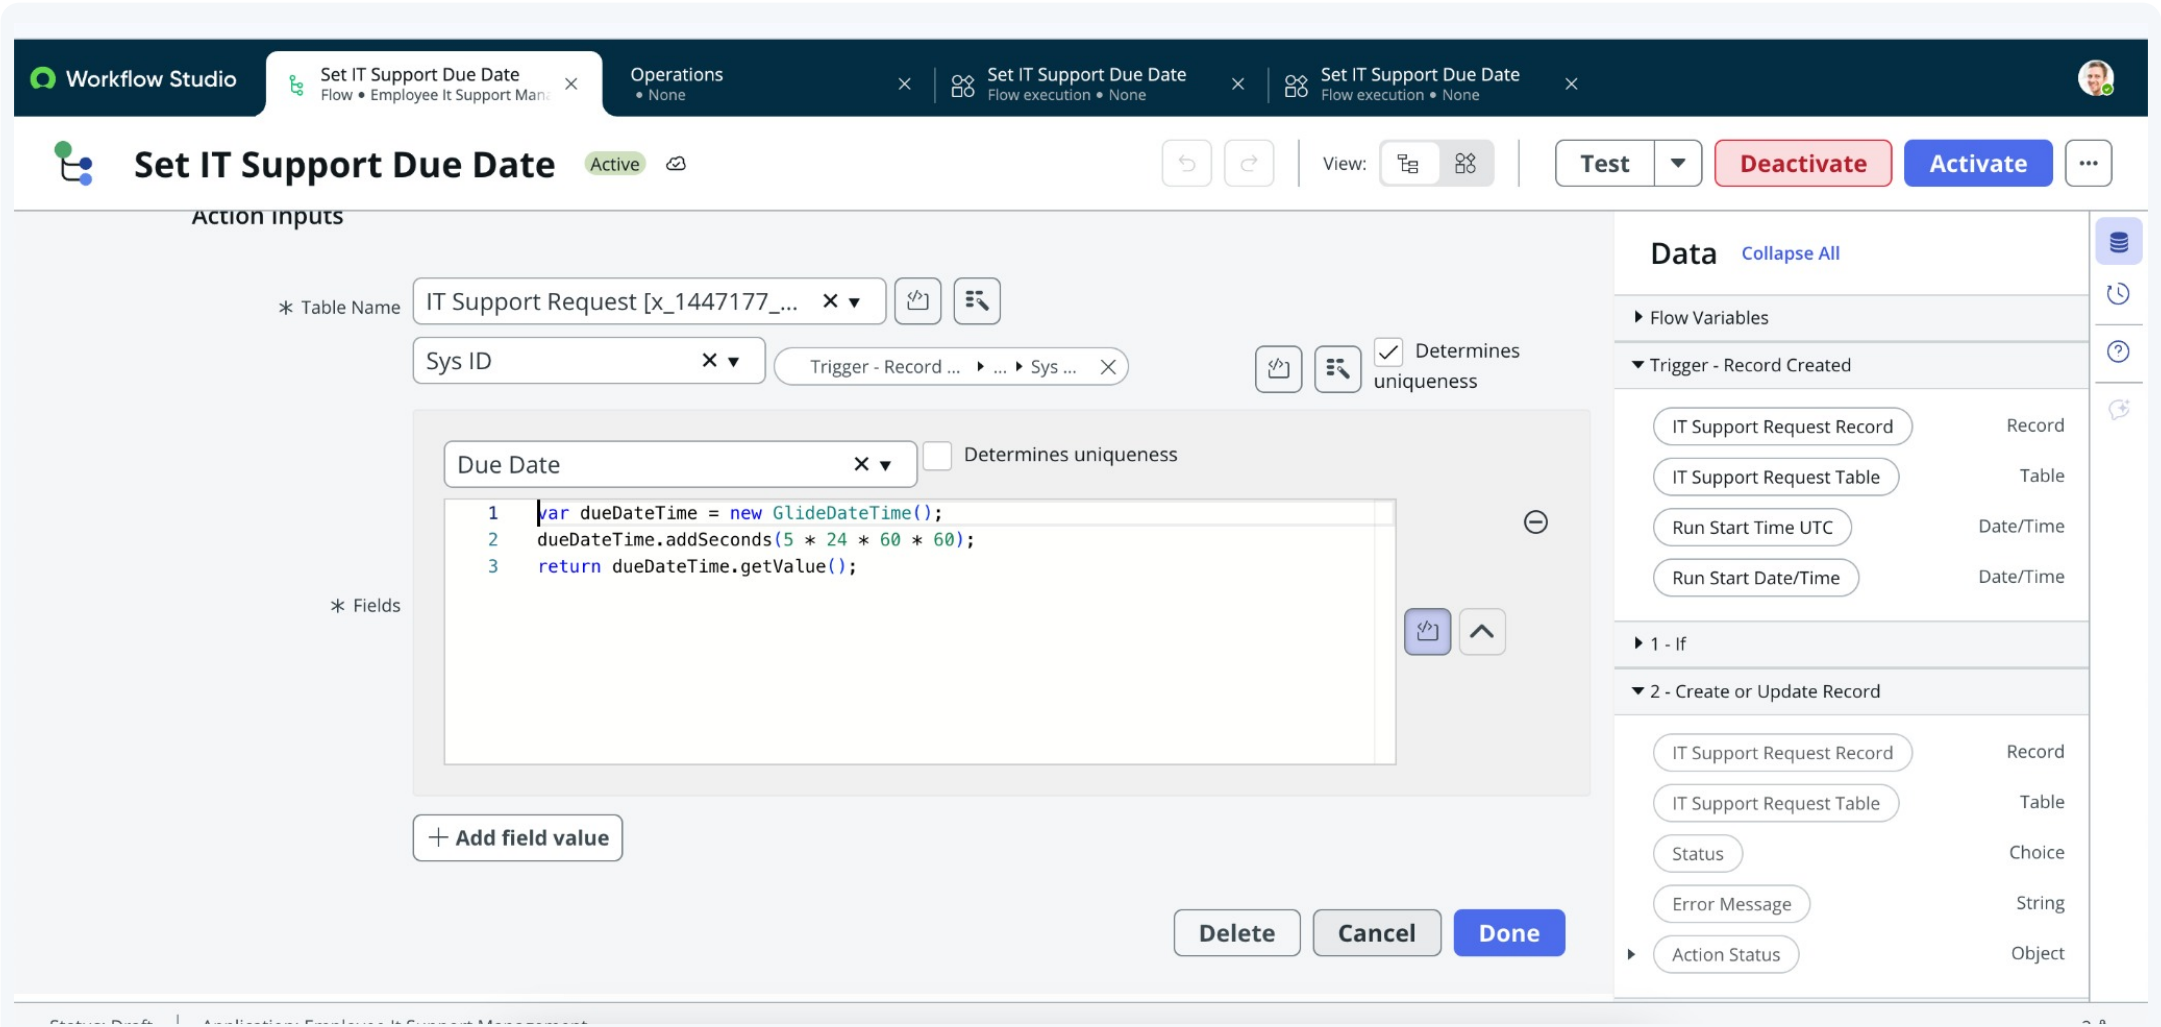

Priority 4 - Low Due Date

WHAT I DID

For Priority 4 requests, I set the target to three days. I converted the three-day target into seconds and added it to the current GlideDateTime value.

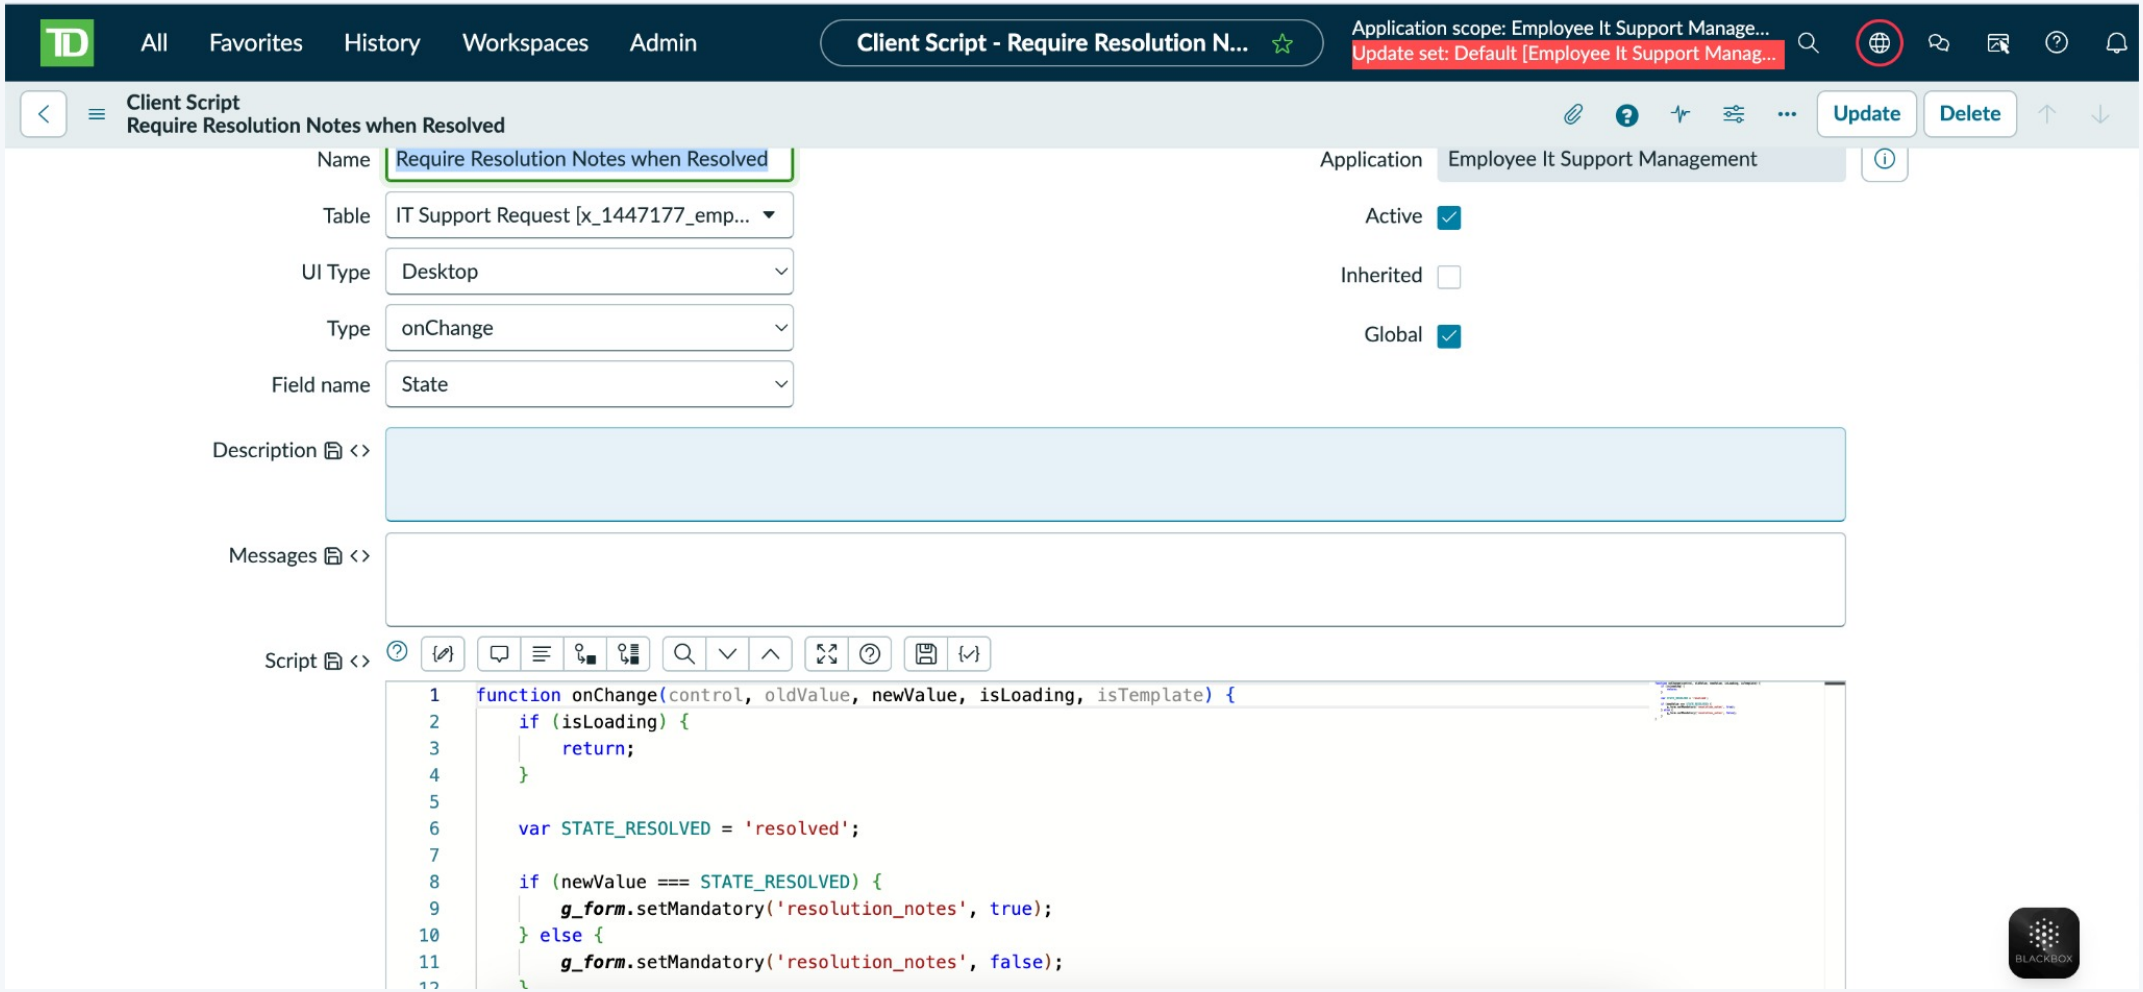

Priority 5 - Planning Due Date

WHAT I DID

For Priority 5 requests, I set the target to five days. This completes the priority-based due-date logic across all five priority levels.

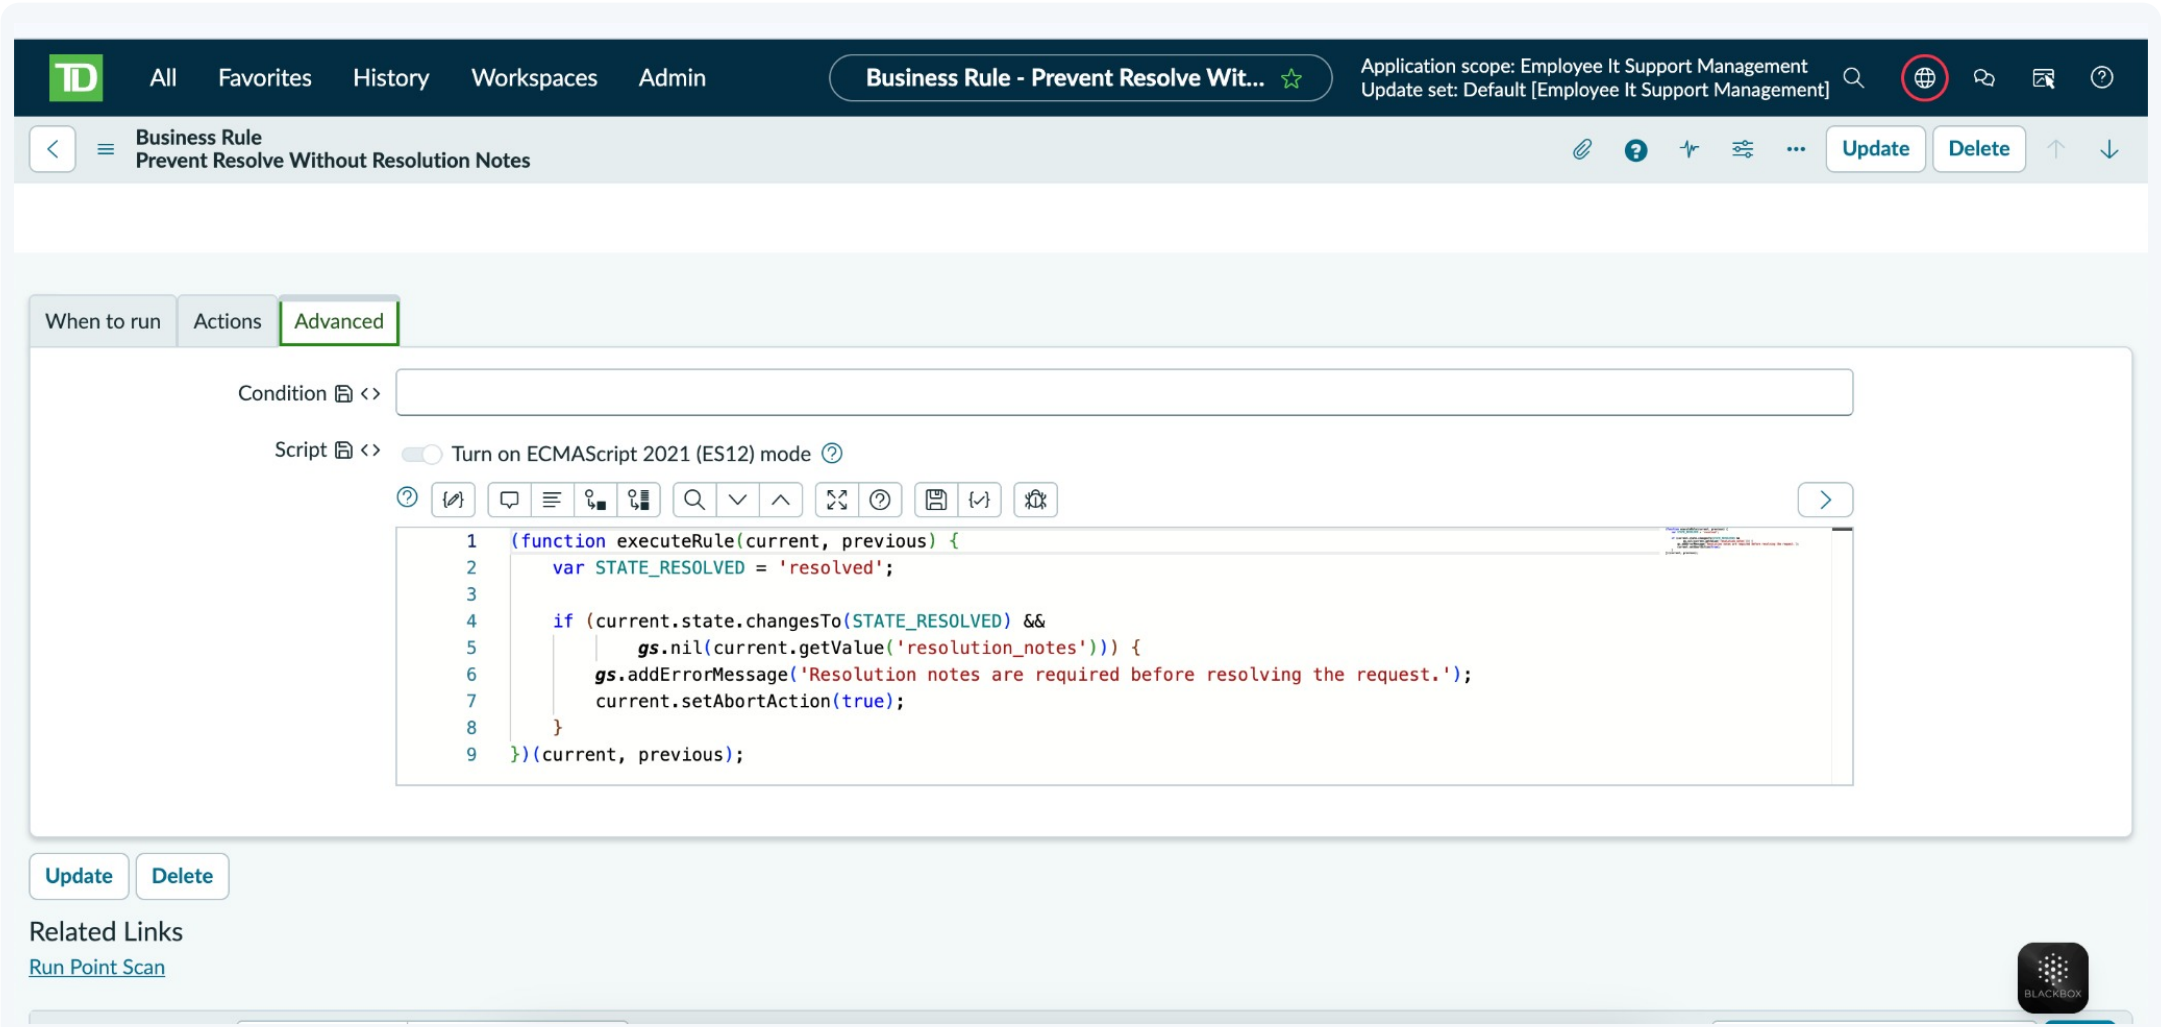

Client Script - Require Resolution Notes

WHAT I DID

I created an onChange Client Script on the State field. When the request changes to Resolved, the script uses g_form.setMandatory('resolution_notes', true) so the agent must enter resolution notes. If the state changes away from Resolved, the field is no longer mandatory.

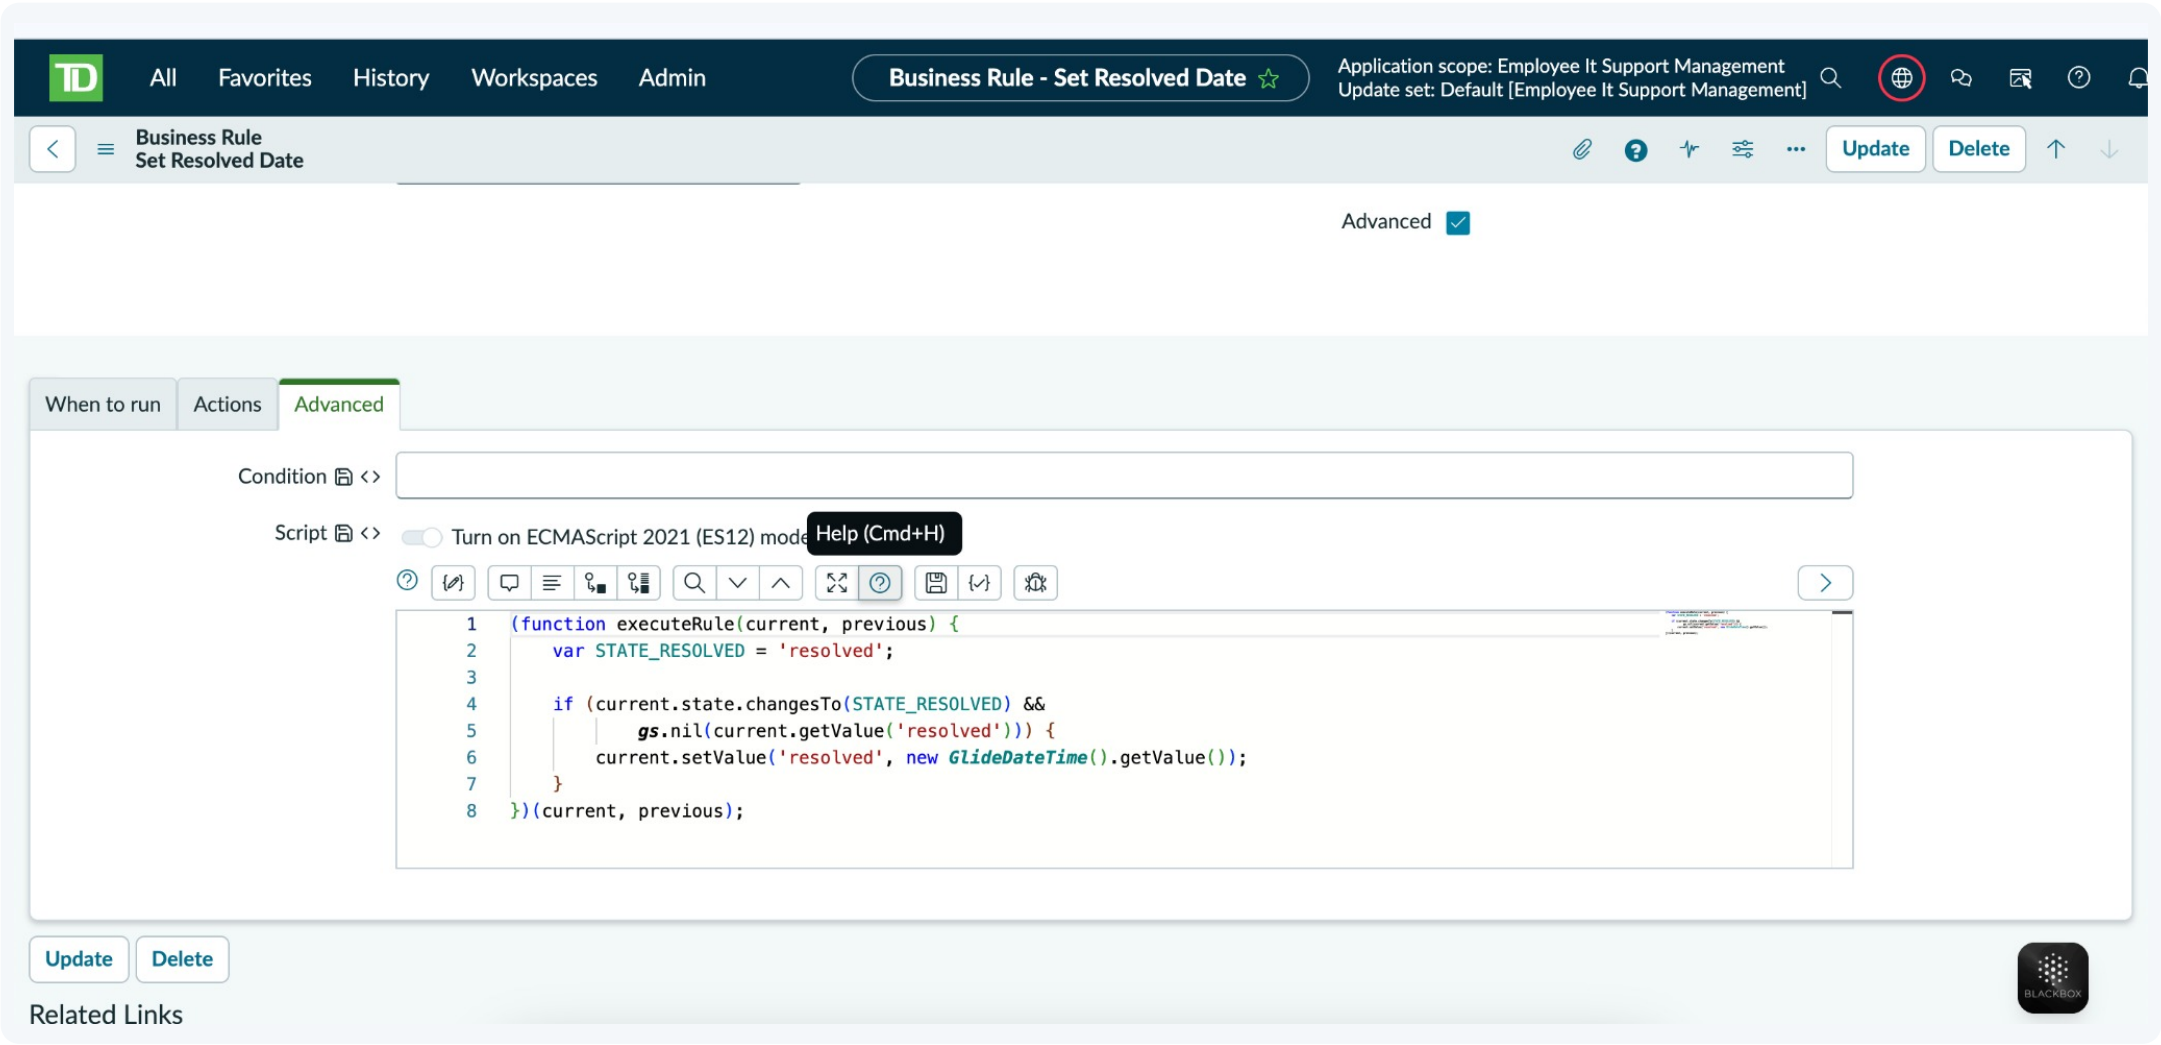

Business Rule - Set Resolved Date

WHAT I DID

I created a Before Update Business Rule that checks whether State changes to Resolved. If the resolved date is empty, I use GlideDateTime to set the current date and time automatically. This avoids asking the agent to enter the resolution timestamp manually.

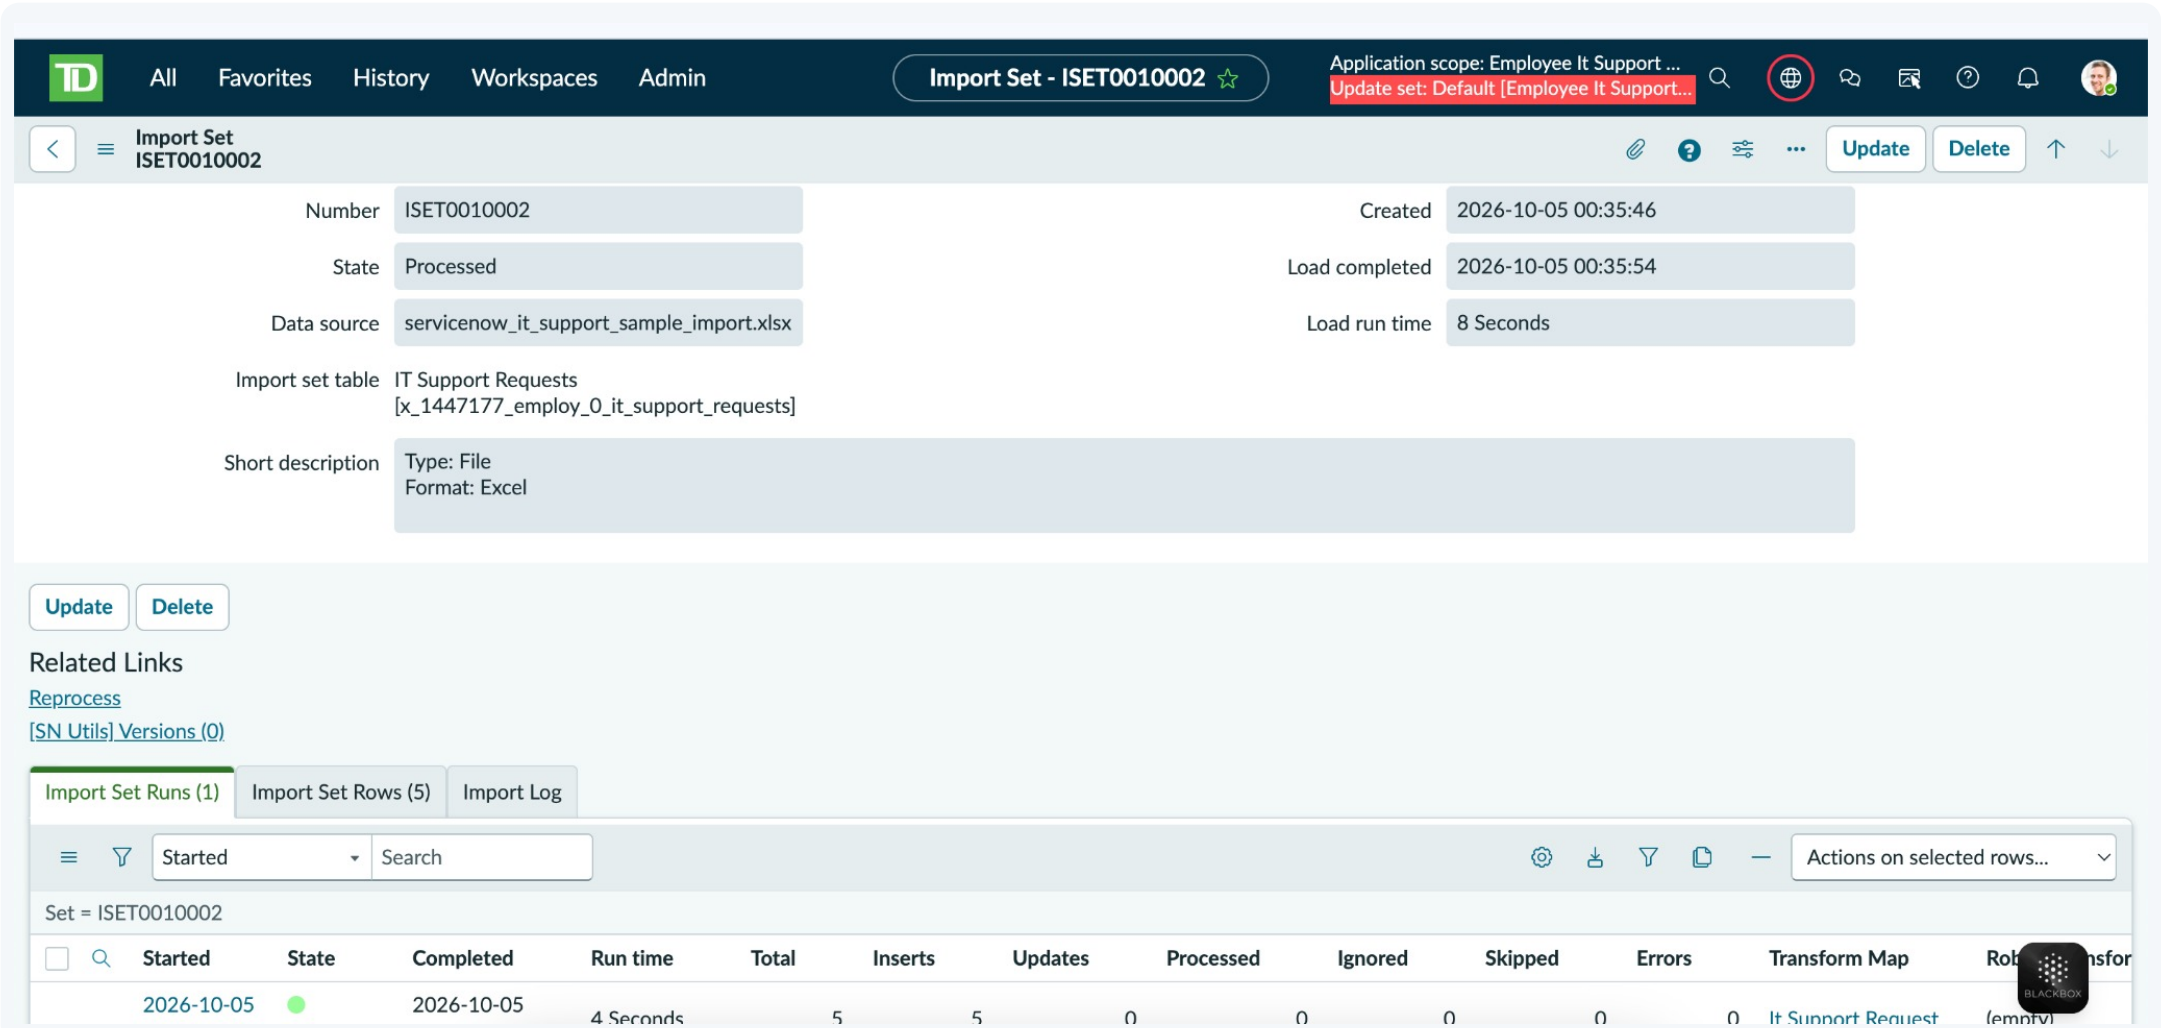

Business Rule - Prevent Resolve Without Resolution Notes

WHAT I DID

I added a second Before Update Business Rule as server-side protection. When State changes to Resolved, the rule checks Resolution Notes. If the field is empty, it displays an error message and calls current.setAbortAction(true) to stop the update. This protects the data even if client-side validation is bypassed.

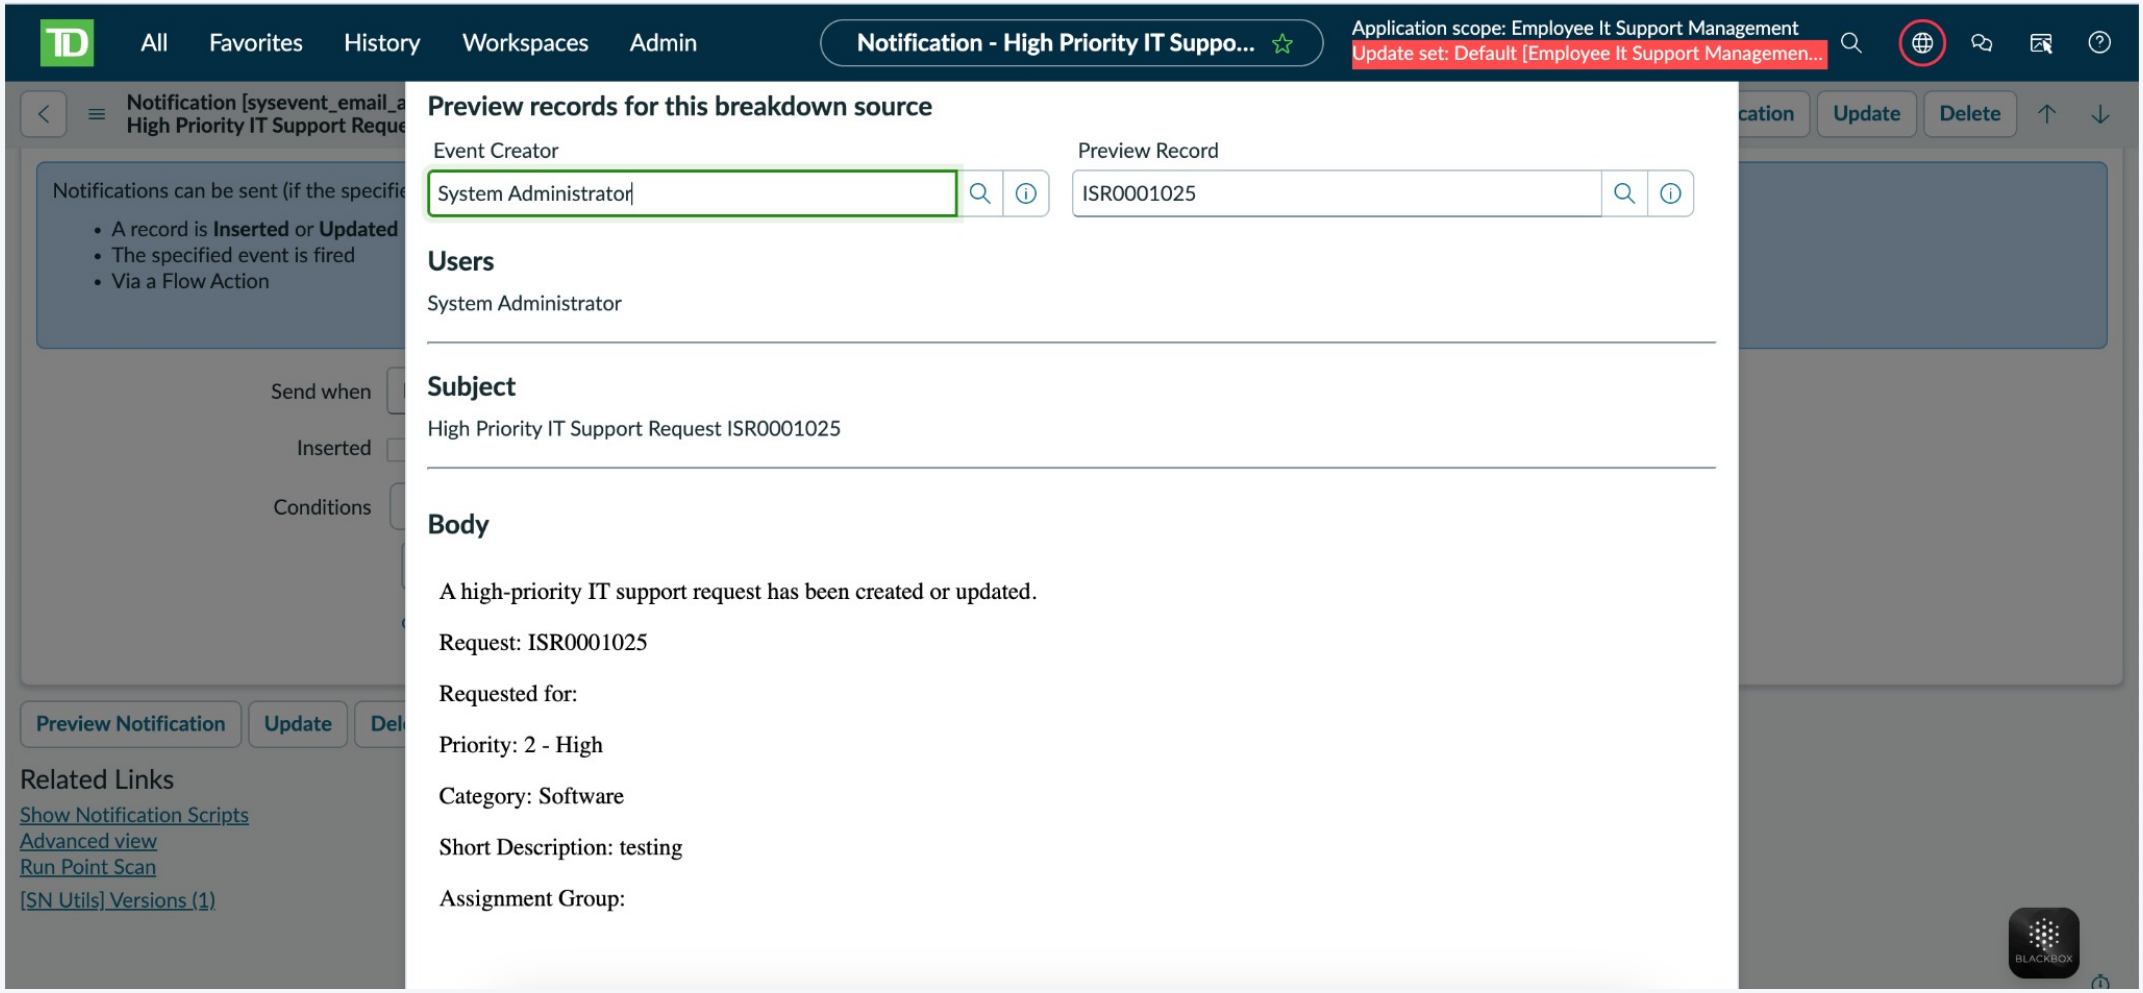

Import Set and Transform Map Result

WHAT I DID

I imported sample IT support data from Excel through an Import Set and used a Transform Map to load the rows into the custom IT Support Request table. I reviewed the Import Set Run and confirmed the records were inserted successfully with no transform errors.

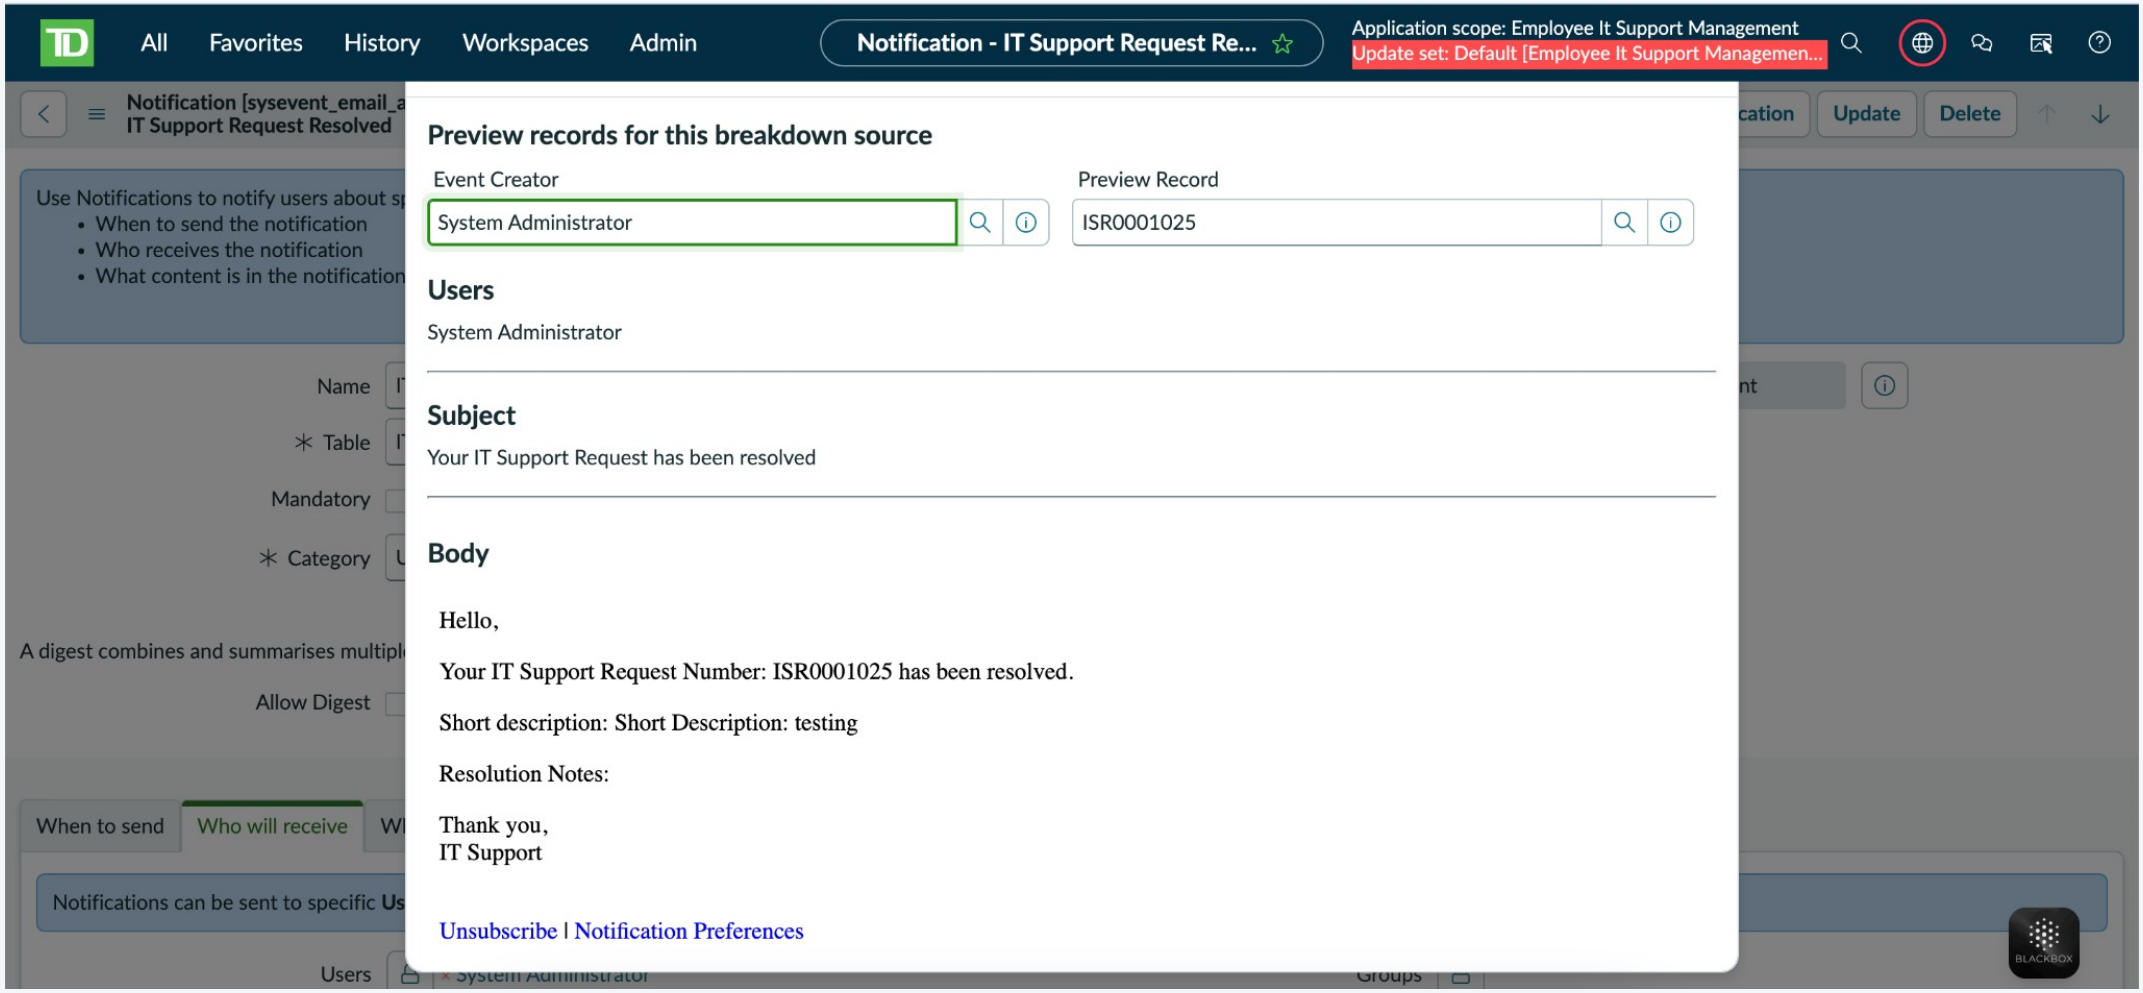

Resolved Request Notification

WHAT I DID

I created a notification that informs the Requested for user when an IT Support Request is resolved. The message includes useful request information so the user can see what was completed and review the resolution details.

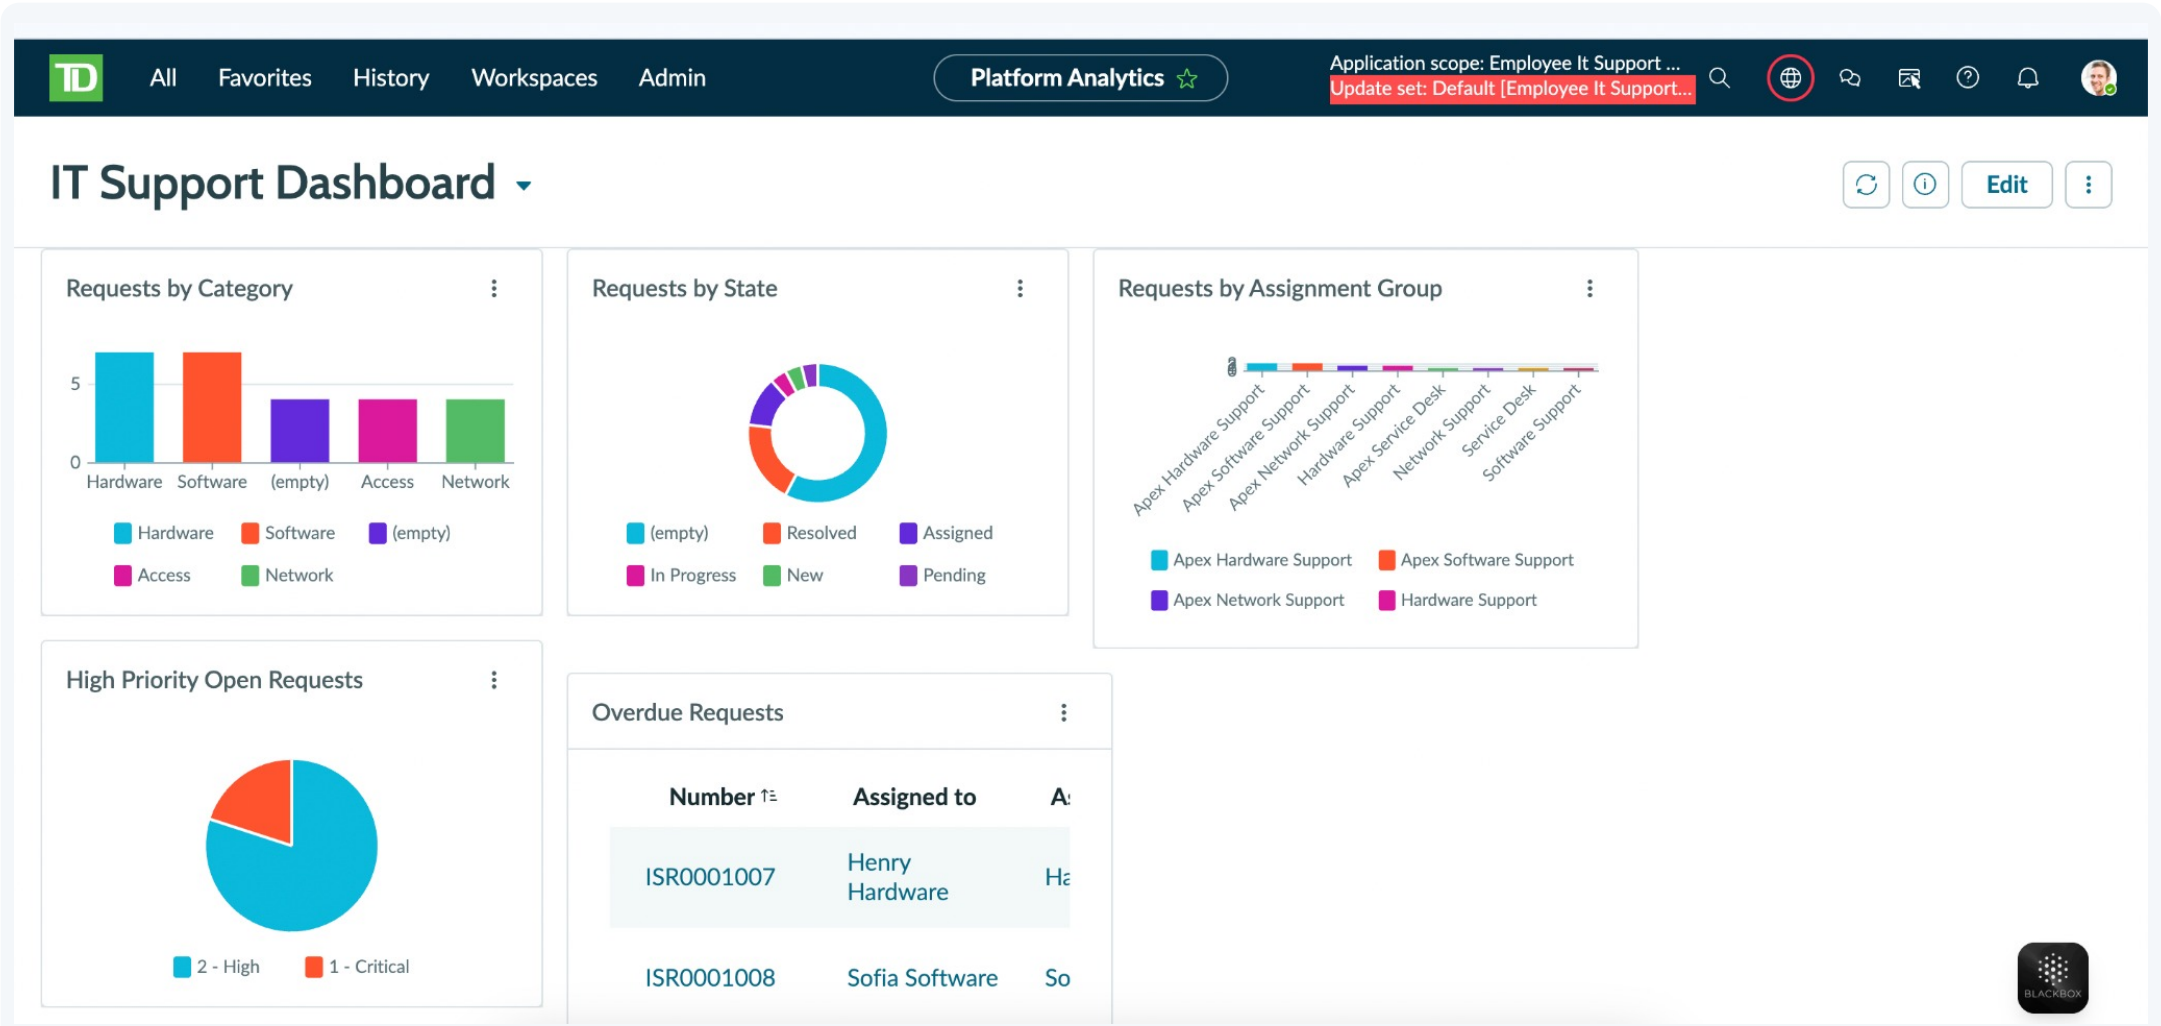

High Priority Request Notification

WHAT I DID

I also created a notification for Priority 1 and Priority 2 requests. I included information such as request number, priority, category, short description and assignment group so important requests are easy to identify.

IT Support Dashboard

WHAT I DID

I created the final IT Support Dashboard in Platform Analytics. It shows Requests by Category, Requests by State, Requests by Assignment Group, High Priority Open Requests and Overdue Requests. This gives a quick operational view of workload, status, routing and aging from the same custom support-request data.

What I completed

- Built a scoped ServiceNow application and custom IT Support Request table.
- Created a user-facing Service Catalog item and mapped submitted variables into custom records.
- Automated category-based assignment across Hardware, Software, Network and Access requests.
- Automated priority-based due dates for all five priority levels using GlideDateTime.
- Added client-side validation with g_form and server-side validation with Business Rules.
- Automatically recorded the resolution timestamp and prevented incomplete resolutions.
- Imported Excel data through an Import Set and Transform Map and verified successful inserts.
- Created resolved-request and high-priority email notifications.
- Built operational reports and a Platform Analytics dashboard.
- Tested the main flows using execution details and sample records.

Project outcome

The finished application connects request intake, automation, validation, communication, data import and analytics into one ServiceNow support-management workflow. I tested each major piece with sample requests and execution results before using the final records in reports and the dashboard.
